The Usefulness of Earnings and Cash flows in Valuing Security Returns: Empirical Evidence for the UK, the USA and France

ABSTRACT

In this dissertation, I proposed to examine and test empirically six major hypotheses that relate to the role of financial information, namely earnings and cash flows, in three major capital markets, two Anglo-Saxon, the UK and the USA and one code law country, France. A theoretical framework is developed to set the groundwork for building up my research hypotheses. I hypothesize that the homogeneity across firms may not hold, due to firm-specific, industry-specific, and country specific differences across firms. The dataset consists of 36,695 USA, 4,234 UK and 1,181 French firm-year observations over the period 1990-98. Multivariate statistical regression analysis is undertaken to test the major research hypotheses.

The major conclusions drawn from the empirical results are summarized as follows. First, results indicate that indeed both earnings and cash flows are taken into consideration by investors in their investment decisions. Second, given cash flows, results show that earnings are always very important to investors and financial analysts for investment purposes; given earnings though results show that cash flows are more important to investors in the Anglo-Saxon countries, possibly due to the lower importance that investors place on the manipulated earnings in these less conservative countries. As far as France is concerned, results reveal that investors place much more attention to earnings and less attention to cash flows. Third, results show that the value relevance of earnings and cash flows is industry specific. Fourth, evidence shows that investors pay more attention to longer-run earnings and cash flows rather than to shorter-run financial information. Fifth, when earnings are transitory (not stable), investors pay more attention to cash flows and less attention to earnings, a result indicating that investors penalize firms with unstable earnings. Sixth, results show that the value relevance of earnings and cash flows is country specific. Specifically, results indicate that earnings are valued more in France and less in the Anglo-Saxon countries, due to the fact that the financial reporting in the Anglo-Saxon countries is much more liberal (less conservative) and managers may manipulate easier financial information. Moreover, as hypothesized, results show that cash flows are the most (least) value relevant in the USA and the UK (France).

In summary, the evidence provided in this dissertation supports that indeed there are substantial differences in the way investors and financial analysts perceive financial information such as earnings and cash flows in the UK, France and the USA. The results of this dissertation should be of great importance to the major stakeholders such as investors, creditors, financial analysts, especially after the latest financial scandals and collapses of giant organizations worldwide. Furthermore, these results support that fundamental analysis does play a very important role in the capital markets and it should be taken more seriously into consideration by the stakeholders for investing, credit, financing and valuation analysis purposes.

The Usefulness of Earnings and Cash flows in Valuing Security Returns: Empirical Evidence for the UK, the USA and France

CHAPTER I. Introduction	1
CHAPTER II. Critical Review of the Value Relevance Literature	10
2.1 Introduction	10
2.2 The value relevance of earnings and cash flows	11
2.3 The role of earnings in the capital markets	13
2.4 The role of the cash flows in the capital markets	22
2.5 The use of contextual factors in improving the association between financial information and security returns	31
2.5.1 The effect of the measurement interval	38
2.5.2 The effect of earnings persistence	39
2.5.3 The effect of firm's growth	40
2.5.4 The effect of firm's size	41
2.5.5 The effect of operating cycle length	43
2.5.6 The effect of aggregate accruals	43
2.6 Summary of the critical review of the value relevance literature	44
CHAPTER III. Critical Review of the International Financial Reporting Literature	47
3.1 Introduction	47
3.2 International classification of financial reporting systems	48
3.3 Financial reporting in France, U.K and USA	53
3.3.1 Financial reporting in France	53
3.3.2 Financial reporting in the UK	56
3.3.3 Financial reporting in the USA	57
3.4 Comparative analysis of the financial reporting systems in the UK, USA and France	59
3.5 Differences in the value relevance of earnings and cash flows between Anglo-Saxon countries (US and UK) and France	71
3.6 Financial reporting in the UK: The Statement of Cash flows (FRS#1)	72
3.7 Comparative analysis of the empirical evidence on the value relevance of earnings and cash flows in the UK, USA and France	75

3.7.1	Empirical evidence on the value relevance of earnings and cash flows in the USA	76
3.7.1.1	When long return intervals are considered	77
3.7.1.2	When transitoriness of earnings is considered	79
3.7.1.3	Level of operating cycle and industry effects	80
3.7.2	Empirical evidence on the value relevance of earnings and cash flows in the UK	81
3.7.3	Empirical evidence on the value relevance of earnings and cash flows in France	83
3.7.4	Comparative analysis	85
3.8	Summary of the critical literature review	88

CHAPTER IV: Theoretical Framework, Motivation for the Study and the Research Hypotheses **90**

4.1	Theoretical Framework on the value relevance of earnings and cash flows	90
4.1.1	Theoretical framework and modeling of contextual factors	102
4.1.1.1	Permanent vs transitory earnings	102
4.1.1.2	Framework on the earnings transitoriness	104
4.1.1.3	Theoretical framework for long return intervals	106
4.1.2	Summary on the theoretical framework	110
4.2	Research hypotheses	111
4.2.1	Hypothesis 1: There exists a positive association between operating earnings (cash flows) and returns in the UK, USA and France	111
4.2.2	<i>Hypothesis 2</i> : Operating earnings (cash flows) are associated with returns, given cash flows (earnings) in the UK, USA and France	112
4.2.3	Hypothesis 3: The relative informativeness of operating earnings and cash flows is industry specific in the U.K, USA and France	114
4.2.4	Hypothesis 4: The value relevance of earnings and cash flows improves as the measurement interval increases.	115
4.2.5	Hypothesis 5: The value relevance of cash flows improves when earnings are transitory	116
4.2.6	Hypothesis 6: The relative informativeness of earnings and cash flows is country specific.	118
4.2.7	Summary of the research hypotheses	119
4.3	Notation of all variables included in the equations	121

CHAPTER V State of the Art Methodologies and Techniques Employed **123**

5.1	Sources of data	123
5.2	Measurement of financial and market variables	128
5.3	Empirical Models	129
5.3.1	Univariate analysis	130
5.3.2	Multivariate regression models	131
5.3.3	Permanent vs transitory earnings models	134
5.3.4	Long windows empirical models	135

5.4	State of the art methodologies employed	136
5.4.1	Methodological technique based on the level and changes of earnings and cash flows	137
5.4.2	Framework for modelling conceptual factors related to permanence	140
5.4.3	Methodology for the long return intervals	143
5.5	Econometric issues and statistical tests	146
5.5.1	Statistical tests applied	146
5.5.1.1	Correlation and coefficient of determination	146
5.5.1.2	The t-test	147
5.5.1.3	The F-diagnostic	147
5.5.1.4	Statistical diagnostic for estimating the t-values of the sum of coefficients	148
5.5.1.5	The Vuong z-statistic	149
5.5.1.6	Statistical diagnostic for calculating means	149
5.5.2	Multicollinearity	150
5.5.3	Heteroskedasticity	151
5.6	Summary of the methodology employed	152

CHAPTER VI: Empirical Results **154**

6.1	Introduction	154
6.2	Regression Diagnostics:	157
6.2.1	Descriptive Statistics	157
6.2.2	Correlation Analysis	158
6.3	Regression analysis results	161
6.3.1	Univariate and multivariate analysis results on the value relevance of earnings and cash flows for the USA, UK and France	161
6.3.1.1	Results related to the level and changes in earnings	164
6.3.1.2	Results related to the level and changes in cash flows	164
6.3.2	Multivariate regression analysis results on the value relevance of earnings and cash flows	165
6.3.3	Statistical analysis results related to the contextual factors	183
6.3.3.1	Multivariate analysis regression results for testing the relative informativeness of earnings and cash flows by industry effects for each country	184
6.3.3.2	Multivariate analysis regression results for examining the informativeness of earnings and cash flows when the measurement interval increases	190
6.3.3.3	Multivariate regression analysis results for examining the informativeness of earnings and cash flows when earnings are transitory	192
6.3.3.4	Multivariate analysis regression results to test whether the valuation of earnings and cash flows is country specific	197

ACKNOWLEDGEMENTS

Any sense of accomplishment must be shared with those made it possible for me to prepare this dissertation and complete my doctoral degree.

I am indebted to Dr. Ephraim Clark, dissertation supervisor. His very valuable advice, keen insight and direction made this effort a very meaningful and enjoyable experience. I would also like to thank the other members of my dissertation committee, Dr. Philip Arestis (Cambridge University), Dr. Bernard Grand (University de Marseille-Aix en Provence, France) and Dr. David North (Middlesex University) for their very valuable advice, co-operation and assistance.

I would also like to thank all my professors at Middlesex University who generously shared their knowledge with me and provided me with the necessary background to conduct this work. Special thanks to the research/graduate administration staff for their valuable support during my studies.

Lastly, I would like to thank my family, especially my daughters Stephanie and Olivia and my husband for their continued encouragement without which this thesis would not have been completed.

**The Usefulness of Earnings and Cash flows in Valuing Security Returns:
Empirical Evidence for the UK, the USA and France**

CHAPTER I

INTRODUCTION

One of the major objectives of financial reporting is to provide useful information to the capital market participants for investing, credit and managerial decisions. Empirical capital markets research examined extensively the type of financial information that could be useful in explaining security returns. The evaluation of earnings usefulness in the capital markets has been among the primary empirical questions raised in several studies in the past three decades. The value relevance of earnings has also been examined recently in conjunction with cash flows (Cheng and Yang; 2003; Ball et al, 2003; Bartov et al., 2001; Ball et al., 2000; Dechow, 1994; Alford, et. al., 1993; among others). Empirical research provided evidence to support that earnings are more useful than cash flows in the capital markets. Existing evidence on the association of operating cash flows beyond earnings in explaining security returns has been inconclusive. Furthermore, to date comparative international research on the value relevance of cash flows has been limited. Ali and Pope (1995), Board and Day (1989) used U.K. data to examine the usefulness of cash flows in the marketplace. The results of these U.K. studies showed that cash flows are not associated with security returns, given earnings. Moreover, the explanatory power of their models was not that strong. These researchers included in their models working capital from operations, a variable shown in prior studies to be highly correlated with operating earnings (Bartov, 2001). Furthermore, Lev (1989) among others, argues that

when researchers use aggregate data, they assume that the relationship between earnings and cash flows with security returns is homogeneous across firms. It should be noted that this assumption that investors react identically to earnings and cash flows of all firms is not that pragmatic.

Indeed, earnings are considered the dominant variable in the marketplace, especially for security valuation, in executive compensation contracts, in debt covenants, for bond ratings, in credit and investment decisions (Ball et al. 2003; Lev, 1989). Although earnings are considered the dominant measure in the marketplace, the existence of information asymmetries between management and the suppliers of capital created a demand by these parties for other measures of performance, especially cash flows. Earnings, cash flows and other measures can be used as a source of information to the suppliers of capital on the firm's ability to generate cash a) for debt repayment, b) for payment of dividends, c) for investing activities, and d) to evaluate management. Since all performance measures are subjective, the suppliers of capital have difficulties assessing the reliability of signals produced by management. Earnings can be criticized because they are affected by arbitrary allocations. Management has some discretion over the recognition of accruals. This discretion can be used by management to signal their private information or to manipulate earnings. If management uses their discretion to manipulate earnings, then earnings will become a less reliable measure of performance and cash flows could be preferable. The question that arises is: Why are cash flows used less often for security valuation purposes? Proponents of cash flows support that cash flows are not affected by arbitrary allocations and are not manipulated by management. On the other hand, cash flows cannot be reported alone because they are influenced by timing and matching problems that cause them to be a noisy measure of firm performance (Dechow, 1994). Dechow states that the revenue recognition and matching principles mitigate the timing and matching problems inherent

in cash flows. Unfortunately, due to inherent limitations, neither of these two measures of performance can be used in isolation for security valuation purposes. Empirical research thus far provided evidence to support that earnings dominate cash flows in the marketplace. Existing evidence though on the incremental information content of cash flows beyond earnings has been inconclusive. The inconclusive results in prior studies, and the limited research on this issue provide motivation for this study.

Furthermore, since earnings have inherent limitations, the UK Accounting Standards Board (ASB) issued in 1991 the Financial Reporting Standard (FRS) # 1 entitled "Cash Flow Statements". The objective of this standard is to provide cash flow information to investors a) to assess the firm's ability to meet its obligations, b) to assess the firm's ability to predict the amount, timing and uncertainty of future cash flows; and c) to assess the reasons for differences between earnings and cash flows. It is also supported by the UK Accounting Standards Board that the cash flow information should be complementary to the profitability information when making an assessment of the organization's future cash flows.

This research study differs from prior studies in the following respects. First, it examines not only the value relevance of operating cash flows beyond earnings, but it also examines the role of cash flows in the capital markets after considering the industrial effects on the relative usefulness of operating earnings and cash flows in explaining security returns. Second, it examines the value relevance of earnings and cash flows when the measurement interval increases. Third, the above major research questions are examined empirically using data from UK and USA (Anglo-Saxon countries) and France (a code law country) in order to determine whether the valuation role of financial information differs in these countries. Fourth, this study examines comparatively the valuation of financial information such as earnings and cash flows, over longer measurement intervals for the UK, USA and France. Thus far, no other study has

examined the above issues using comparative statistics for the U.K, US and France. Since there are several financial reporting, economic and social differences between the above countries, it is expected that this study will provide new insight regarding the effect, if any of these differences, on the value relevance of earnings and cash flows in these countries.

The present study hypothesizes that the homogeneity across firms may not hold, due to firm-specific, industry-specific, and country specific differences across firms. More specifically, it is hypothesized that the association of operating cash flows and earnings with security returns is affected by the industry and the country the organization belongs to. Regression models will be employed to examine the value relevance of earnings and cash flows in the capital markets for the period 1990-1998. The sample firms will be collected from the Global Vantage and Compustat Databases. The aggregate data will be broken into three industries, according to the Standards and Poors Industrial classification. Standards and Poors classifies organizations into the following three major industrial groups: i) manufacturing; ii) retail; and iii) services.

Statistical analysis was undertaken in this dissertation to test the major hypotheses. A sample of 36695 USA, 4234 UK and 1181 French firm year observations was used to test the research hypotheses. The major conclusions of the empirical results are summarized as follows.

First, regarding hypothesis one which stated that earnings and cash flows are associated with stock prices in USA, UK and France, results indicate that indeed both earnings and cash flows are taken into consideration by investors in their investment decisions.

Second, regarding hypothesis two, which stated that earnings are valued by investors beyond cash flows and moreover, cash flows are valued by investors beyond earnings, my statistical analysis revealed the following: given cash flows, earnings are always very important to investors and financial analysts for investment purposes; given earnings though results show that cash flows are important to investors in the Anglo-Saxon countries USA and UK possibly

due to the lower importance that investors place on the manipulated earnings in these less conservative countries. As far as France is concerned, results reveal that investors in that conservative country place much more attention to earnings and little or no attention to cash flows.

Third, As far as hypothesis three is concerned, which states that investors place different attention to financial information such as earnings and cash flows, depending on the industry they analyze, results of this dissertation support this hypothesis. Specifically results indicate that consistent with my hypothesis and my expectations, the statistical results indicate that earnings and cash flow information is industry specific, that is investors and financial analysts pay different attention to earnings and cash flows depending on the industry they analyze. Specifically, investors value more the earnings in the service industry, partly because in that industry the manipulation of earnings is the least because there exist the least accruals (i.e., depreciation, amortization, inventories, etc). As far as the cash flow information is concerned, results indicate that investors value cash flow more in the manufacturing industry. This is not surprising, because in that industry investors and financial analysts expect greater manipulation of earnings due to much higher accruals (i.e., depreciation, amortization, inventories, etc), and thus analysts pay less attention to earnings and consequently pay more attention to cash flows.

Fourth, as far as hypothesis four is concerned, which states that investors pay more attention to longer-run earnings and cash flows rather than to shorter-run financial information, my statistical results for the three countries support this hypothesis.

Fifth, as far as hypothesis five is concerned, which states that when earnings are transitory (not stable), investors are expected to pay more attention to cash flows and less attention to earnings, the statistical results of this dissertation support this hypothesis. Specifically results show that investors penalize firms with unstable earnings and simultaneously these investors

pay more attention to cash flows in making their investment decisions in all three countries.

Sixth, as far as hypothesis six is concerned, which states that investors and financial analysts pay different attention to financial information, such as earnings and cash flows, depending on the country their investment decision relates to, my statistical results support this hypothesis. I hypothesized that the value relevance of earnings will be the highest in France since it has the most conservative financial reporting system. On the other hand, I expect that the value relevance of earnings will be the lowest in the UK and USA because they have the least conservative financial reporting system. Hence, I expect that cash flows will be the most (least) value relevant in the USA and UK (France). Specifically results related to this hypothesis support the following:

i) univariate results indicate that even though earnings and cash flows are important to investors and financial analysts in all three countries, the level of earnings is considered somewhat more important to French investors than to investors in the USA and UK,

ii) univariate results support my hypothesis that cash flows are valued in all three countries but they are valued more by the investors in Anglo-Saxon countries than in non Anglo-Saxon countries like France,

iii) multivariate results support again my hypothesis that the investors in these countries value differently financial information such as earnings and cash flows due to the financial reporting differences in these countries. Specifically, results indicate that earnings are valued more in France and less in the Anglo- Saxon countries. This result may be due to the fact that the financial reporting in the Anglo- Saxon countries is much more liberal (less conservative) and managers may manipulate easier the financial statements,

iv) multivariate results support again my hypothesis that the investors in these countries value differently cash flows due to the financial reporting differences in these countries.

Specifically, results indicate that total cash flow is valued by investors in all three countries, but results show that cash flows are valued more in the Anglo-Saxon countries and less in France. These results may be due to the fact that the financial reporting in the Anglo-Saxon countries is much more liberal (less conservative) and managers may manipulate easier the financial statements, and since earnings are expected to be of lower quality in these countries, financial analysts and investors are expected to pay more attention to cash flows,

v) when earnings and cash flows are taken together by investors and financial analysts, these stakeholders pay more attention to earnings in France and less attention to cash flows in France. The opposite happens in the Anglo-Saxon countries USA and UK. These results are consistent with the previous discussion. As far as the importance of cash flows is concerned, when earnings are considered, results are consistent with my expectations that is, cash flows are more important in the Anglo-Saxon countries USA and UK than in France, when earnings and cash flow information is evaluated simultaneously by investors it is perceived more important in France rather than in Anglo-Saxon countries. These results are possibly due to the fact that in Anglo-Saxon countries, there are greater manipulations of financial information by managers,

vi) regarding industry differences within a country, my statistical results supported that earnings and cash flows are industry specific and moreover these results were also shown to be country specific. Specifically, results showed that in all industries the French model had the highest explanatory power as measured by the well known R^2 . This result was mostly due to the more usefulness of earnings to investors in France. Also, as expected, results indicate that the cash flow information is more useful to UK and USA investors than to French investors in all industries examined, and more importantly in the manufacturing and retail industries where more discretion and manipulation exists in their financial reporting systems;

vii) when I examined the importance of earnings and cash flows in all three countries

over a longer period of time (more than a year and up to five years), my results again supported the hypothesis that investors in these three countries perceive earnings and cash flows differently.

Interestingly, the importance of earnings and cash flows from one to five years, as measured by the R^2 , increases the highest in the USA (almost quadruples, 7% to 27.8%), whereas increases the least in France (almost triples, 11.4% for the annual and 32% for the five year interval). These results are not that surprising that in Anglo-Saxon countries such as the US and UK the increase is greater than in a code law country such as France. This is due to the fact that in the shorter run there is a greater manipulation of financial information in Anglo-Saxon countries than in more conservative countries such as France,

viii) when I examined the importance of earnings and cash flows to investors and financial analysts in cases where the earnings information is transitory (ie., non stable or with very high variability), my results indicate that earnings and cash flows are perceived differently by investors, depending on the country they belong to. Specifically, when earnings are transitory, investors in Anglo-Saxon countries penalize more these firms because the effect of earnings on stock returns is much more negative;

ix) as hypothesised, results support that when earnings are transitory, investors and security analysts in the UK and USA pay more attention to cash flows. These results are very interesting because they show that in Anglo-Saxon countries such as the USA and UK, investors pay additional attention to cash flows because they know that earnings are of lower value when they are unstable. On the other hand, consistent with my expectations, French analysts and investors do pay more attention to earnings because their code law system makes financial reporting in France much more conservative, and thus the variability of earnings is not that high as the variability of earnings in the UK and USA.

In summary, evidence provided in this study supports that indeed there are substantial

differences in the way investors and financial analysts perceive financial information such as earnings and cash flows in UK, France and USA.

The dissertation proceeds as follows: Chapter II critically evaluates the capital markets literature related to earnings and cash flows and it also examines the major differences in financial reporting between UK, USA and France. Chapter III provides a critical review of the International financial reporting literature. Chapter IV discusses the theoretical framework, motivates this study and develops the research hypotheses. Chapter V describes the sources of data, measurement of financial and market variables, the statistical models used to test the research hypotheses of the study, and it also discusses the state of the art methodology and techniques applied. The empirical results (aggregate, by industry, and by country) are discussed in Chapter VI. The conclusions will be presented in Chapter VII.

CHAPTER II

CRITICAL REVIEW OF THE VALUE RELEVANCE LITERATURE

2.1 Introduction

This chapter critically evaluates the literature that relates to the value relevance of financial information (earnings and cash flows). Specifically, it provides an in depth discussion of the significance of earnings and cash flows in the capital markets, In addition, it discusses and critically evaluates the existing empirical studies that were undertaken worldwide which examine the association between earnings, cash flows and security returns.

More specifically, the following subsections follow:

1. The role of financial information in the capital markets: The value relevance of earnings and cash flows
2. The role of earnings in the capital markets
3. Empirical evidence on the usefulness of earnings and cash flows in the capital markets.
4. The use of contextual factors in improving the association between financial information and security returns

2.2 The value relevance of earnings and cash flows

Financial theory suggests that security prices relate to future expected cash flows. Since the aforementioned cash flows are ex-ante, there is controversy in the finance and accounting literature regarding the usefulness of two of the major financial variables, namely earnings and cash flows, in signalling these future cash flows (Dechow, 1994). Researchers examined several empirical questions regarding value relevance of earnings and cash flows in the marketplace, among those the following: i) Do accruals explain differences across firms in the market value of equity, given operating earnings?¹, ii) Do accruals explain differences across firms in the market value of equity, given operating cash flows?, iii) Do accruals and cash flows provide the same information to the market about future expected cash flows? Though evidence exists to support the association between earnings and stock prices, financial analysts and researchers have questioned the relevance and reliability of earnings mainly because i) of their accrual components, and ii) they are manipulated by managers (Xue, 2004; Dechow et al. 2003; Lara et al. 2005).

Earnings are of primary importance to managers, because managerial executive compensation contracts are usually based on earnings. Managers select financial reporting methods to maximize the value of their bonus awards through incentives created by bonus schemes. In addition, managers indulge in income smoothing, that is, taking actions to dampen fluctuations in their organization's earnings, as investors pay more for a firm with a smoother income stream (Dechow et al. 2003; Barth et al. 2005).

Regulatory bodies in Anglo-Saxon countries, such as United Kingdom, Australia, New Zealand, U.S.A. and Canada, and the International Accounting Standards Committee issued cash

¹ Accruals are defined as the sum of a) non-cash expenses/revenues and b) changes in working capital (receivables, inventory, payables), except for changes in cash and cash

flow reporting statements, which support the view that cash flows, in addition to earnings, is useful for security valuation purposes. Even though there has been increased support for the possible usefulness of cash flows in the marketplace, earnings is considered the primary financial measure of performance (Dechow, 1994). For example, the financial press (e.g., Wall Street Journal, Financial Times, etc) publishes earnings prior to cash flow information, an indication that the demand for information about earnings may be greater than the demand for cash flow information. There has been also a greater demand from the investors and financial analysts for earnings forecasts than cash flow forecasts.

Furthermore, research studies emphasized the differential usefulness of earnings and cash flows in explaining stock returns. Literature offers the following explanations.

1. Quality of earnings: according to the quality of earnings explanation, accruals are expected to have a smaller impact on security returns than operating cash flows because accruals represent indirect links to future cash flows. Moreover, there exists empirical evidence which supports that accruals are subject to managerial manipulation (Xue, 2004; Dechow et al. 2003; Barth et al. 2005; Dechow, 1994; Ali and Pope, 1991).

2. Macroeconomic conditions:

- a. Economic downturn: differential stock market reactions of accruals and cash flows may be due to how well organizations anticipate and adjust to changing economic conditions.

- b. Economic expansion: markets may react favourably to accruals when management uses cash to increase non-cash working capital. The reverse is true for recessionary periods.

Even though earnings are considered the dominant financial variable in the marketplace, there exists evidence that earnings are manipulated by managers, because earnings are used in executive compensation contracts, and that managers believe that investors pay more for a firm

equivalents.

with a smoother income stream.

The inconclusive empirical evidence regarding the usefulness of cash flow and accrual measures for valuing the firm, as well as the increasing interest in cash flow reporting, provide motivation for research in this area.

2.3 The role of earnings in the capital markets

Since the seminal work of Ball and Brown (1968) earnings have been the dominant financial measure in the capital markets. Assessing the usefulness of earnings to investors is important, since earnings are widely believed to be the premier information item provided in financial statements (Lev, 1989). Equity valuation models use expected earnings as an explanatory variable, financial analysts express their beliefs about future outcomes of securities in the form of earnings forecasts, management decisions and their compensation are often stated in terms of earnings objectives.

Earnings' usefulness can be derived from the estimation of correlation between stock returns and earnings. If the information contribution of earnings to investors is *significant*, earnings are powerful, otherwise not. This points to the consideration of the returns/earnings correlation, or the R^2 of the regression, as a measure of the information contribution of earnings to investors. It was found that the returns/earnings R^2 is not a complete measure of the usefulness of earnings due to differences in the returns/earnings relation (Lev, 1989). Even though, it captures a very important attribute of earnings — their ability to facilitate the prediction of future security returns.

In the early 1980s, a line of research introduced firm characteristics to explain cross-sectional differences in the returns/earnings relation. The factors examined by these studies

include size (Atiase, 1985), predictability of earnings (Pincus, 1983) , stock exchange market (Grant, 1980) , and prior information disclosure environment (McNichols and Manegold, 1983). Although these studies contributed to our understanding of the differences in the returns/earnings relation across firms, they were not in general based on a theoretical formulation of the returns/earnings relation.

Lev (1989) summarized various relevant characteristics and findings of a sample of studies for the period 1980-88. Lev analyzed several issues in order to evaluate the usefulness of earnings: return window, profitability ratios, incorporate earnings-related items (cash-flow components, sales, expenses). This line of research uses unexpected earnings (quarterly and annual) rather than reported earnings: stock prices reflect expectations about future earnings before earnings are announced so, it seems reasonable to correlate the change in price (return) with unexpected earnings (new information), rather than with reported earnings. This methodology is expected to increase the power of the returns/earnings analysis. Initially, Lev critically analyzed studies that used cross-sectional analysis to determine the value relevance of earnings. The R^2 was found to be very low: only 2-5% of the cross-sectional variability of returns could be ascribed to the unexpected earnings information. Then Lev regressed quarterly earnings of 194 firms listed on the quarterly Compustat tape for the period of 1980-87. Time-series' returns/earnings regressions have the same results as the cross-sectional regressions. Even though these prior studies established an association between earnings and security returns, the explanatory power of earnings was found to be relatively low.

In the late 1980s, in the 1990s and in the early 2000s, studies have progressed into a new research arena. These studies are divided into theoretical and empirical. The theoretical studies are divided into two subgroups: studies that assumed joint normality of cash flows and those based on time-series process of earnings. Assuming joint normality of cash flows, the

researchers run linear regressions where x is the future cash flows and y the earnings signal. The slope coefficient β is the theoretical earnings response coefficient (ERC). ERC is defined as the effect of a dollar of unexpected earnings on stock returns, and is measured as a slope coefficient in the regression of abnormal stock returns on the appropriately scale unexpected earnings. Two theoretical conclusions derived from joint normality are: the larger the future uncertainty, the larger the ERC and the noisier the firm's reporting system, the smaller the ERC (Cho and Jung, 1991). Assuming time-series based valuation and based on the Beaver, Lambert, and Morse (BLM), (1980) study, the observed earnings y_t are taken as a mixture of ungarbled earnings x_t and earnings with no pricing implication ε_t . They have made the valuation assumption for each security and derived the relationship that the percentage change in price equals the percentage change in expected ungarbled earnings. Combining BLM specifications with other expressions and functions such as expected dividends and earnings multiplier λ , the major conclusions derived are: "ERC is a function of the earnings multiplier λ and the expected rate of return used to discount earnings. Since the expected rate of return is expressed as a function of systematic risk (β) and the risk-free interest rate under CAPM, ERC is a decreasing function of systematic risk and interest rate" (Cho and Jung, 1991, p.85).

Concerning the empirical studies that were undertaken thus far, they are classified into two major groups: studies on ERC determinants and studies on the informativeness of earnings. The main objective of ERC determinant studies is to identify factors that affect ERC over a long-term window. Earnings informativeness studies examine the effect of a certain event on the change in ERC over a short-term window. In the literature, the determinants studies are generally referred to as *association studies* and the informativeness studies are referred to as *event studies*. Although most association studies use a long return window, while event studies use a short window, there is no theoretical reason why they should not use alternative return windows. The

results of some studies are not consistent with each other when their length of return window is different (Easton, Harris and Ohlson, 1992; Dechow, 1994).

Researchers concluded that the ERC related studies have some limitations: 1) theoretical studies are based on strong assumptions and it is not clear how the parameters of the models will be changed when these assumptions are relaxed², 2) empirical tests also have various limitations. Most of the studies focus on uncertainty of future earnings or earnings' quality. It is difficult to find approximate proxies because the two factors are related to each other. No studies have attempted to segregate the effect of each component, 3) Another limitation is that it is not clear yet which of the two models, information economics based model or time-series based model, better describes reality. Researchers support that these models will be more refined when we know more about the links between earnings and dividends and current and future earnings.

Regarding the association studies, several researchers examined the relationship between earnings and security returns, among those Alford et al (1993), Board and Day (1989), Easton and Harris (1991) and Freeman (1987). Easton and Harris (1991) first introduced in their models changes in earnings. They supported that in multiple regression of security returns, on both the current earnings levels and earnings change variables, both coefficients are generally significantly different from zero. This result suggests that both earnings variables play a role in security valuation. Ohlson and Shroff (1992) corroborated their results. The study of Alford et al (1993) compares and contrasts the information content and timeliness of accounting earnings for several non-US countries using matched US samples as the benchmark. The results presented a considerable variation in explanatory power of earnings across countries. In addition the findings of Lev's (1989) study support that the returns/earnings relation shows considerable

² For example, theoretical models are based on economic earnings or expected future cash flows, where as

instability over time, meaning that the usefulness of quarterly and annual earnings to investors is very limited. This evidence is also supported by the low correlation between earnings and returns. Lev shows that earnings have low information content because of the discretion of managers regarding the valuation principles, the accounting measurement, and the manipulation of earnings. Table 1 also presents a summary of major results of selected prior studies.

The aforementioned studies emphasize earnings usefulness. On the other hand researchers criticized earnings because there is evidence that they are manipulated (Cheung et al, 1996). Therefore, additional studies examined the usefulness of other measures of firm performance, mainly cash flows. These studies are discussed and analyzed in the section that follows.

empirical models proxy these variables with accounting earnings and operating cash flows.

TABLE 1 : Review of the literature: Major results of selected prior empirical studies (in alphabetical order)

Authors	Results
Alford et al (1993)	<ul style="list-style-type: none"> This study compares the information content of accounting Earnings for several non-US countries using matched US samples as the benchmark. The results presented a considerable variation in explanatory power of Earnings across countries. Accounting Earnings prepared in accordance with the domestic GAAP of Australia, France, Netherlands and UK are more timely or more value relevant than accounting Earnings prepared in accordance with US GAAP. The results for Belgium, Canada, Hong Kong, Ireland, Japan, Norway, South Africa and Switzerland are not conclusive. Accounting Earnings for Denmark, Germany, Italy, are either less timely or less value relevant than US GAAP Earnings.
Ali and Zarowin (1992)	<ul style="list-style-type: none"> For firms with permanent Earnings in the previous period, the incremental explanatory power and the increase in ERC are small when the Earnings level variable is included in the model. For firms with transitory Earnings in the previous period, the incremental explanatory power and the increase in ERC from the inclusion of Earnings level variable are much larger.
Ali (1994)	<ul style="list-style-type: none"> Used a model that allows non-linearity between Returns and Earnings, WCFO and CFO. The results indicate that these three variables have incremental information content. The incremental information content of Earnings, WCFO and CFO declines as the absolute value of changes in these variables increases.
Ali and Hwang (2000) Ali and Pope (1995)	<ul style="list-style-type: none"> Their results show that the degree of association between security returns and earnings is lower in code law countries as opposed to common law countries. More precisely, earnings in code law countries like France seemed more conservative and consequently less timely than those in common law countries, such as USA and UK. Earnings, Funds Flows and Cash Flows have explanatory power for returns individually and the response coefficient of their unexpected components is positive. Earnings have value relevant information content beyond Funds Flows and Cash Flows. The inclusion of both levels and changes of Earnings and the use of time varying coefficients and non-linear models, increase the explanatory power of the Earnings/ Returns model. The power of the model is decreased when they used Funds Flows and even more when they used Cash Flows from Operations.
Ball, Kothari and Robin (2000)	<ul style="list-style-type: none"> Results indicated that earnings in code law countries, such as France, is less timely and less conservative than common law income as reported in UK and USA. Comparing the UK and USA evidence, results indicate that there is less asymmetric conservatism in the UK earnings.
Bartov et al (2001)	<ul style="list-style-type: none"> Their results indicated that earnings in Anglo-Saxon common law countries have more explanatory power than cash flows. Conversely, in the two code law countries (Japan and Germany), earnings are not superior to cash flows in explaining security returns.
Bernard and Stober (1989)	<ul style="list-style-type: none"> Their goal was to assess the generality of Wilson's results by contacting the same tests over 32 quarters. Their research showed that Wilson's results don't robust over larger time frames. They investigated the effect of firm size on the relation between Returns and Cash Flows. No obvious pattern in the results across the different firm sizes since they didn't find enough evidence to support that information about unexpected Cash Flows/ Accruals was more likely to be impounded in market prices for small and medium size firms than for large size firms.

TABLE 1 (continued)

Authors	Results
Board and Day (1989)	<ul style="list-style-type: none"> • There is considerable evidence of a consistent information content both in the traditional return on investment measure and in the working capital based measure of Cash Flow. • There is no evidence of information content in the net cash assets Earnings figures. • There is some evidence that the Return on investment figures yield more information than either the working capital based measure of Cash Flow and the net cash assets Earnings figures. • There is little evidence that the information content of any of the Earnings figures is substantially influenced by inflation. • There is some evidence of a time effect on the information content of Earnings measure and this does not appear to be wholly caused by inflation.
Bowen et al (1987)	<ul style="list-style-type: none"> • Cash Flows have incremental information after controlling for the association between Security Returns and Cash Flows. • Cash Flow data have incremental information content conditional on both Earnings and WCFO. • There is little evidence that WCFO has incremental information content relative to that contained in Earnings.
Chan and Seow (1996)	<ul style="list-style-type: none"> • They reported stronger association for Returns / Earnings relations using foreign GAAP Earnings than for those using Earnings adjusted to US GAAP.
Chan et al (1991)	<ul style="list-style-type: none"> • The findings reveal a significant relationship between Earnings yield, size, book to market ratio and cash flow yield and Expected Return in the Japanese market. • Of the four variables the book to market ratio and Cash Flow yield have the most significant positive income on Expected Returns. • Small firms in our sample tend to outperform larger firms, after adjusting for market risk and the other fundamental variables. • Of the four variables considered, it is hardest to disentangle the effect of the Earnings yield variable.
Charitou (1997)	<ul style="list-style-type: none"> • Operating Cash Flows have information content beyond Earnings in explaining security Returns. • Cash Flows play a more important role in the market place, the smaller the absolute magnitude of accruals, the longer the measurement interval and the shorter the firms Operating Cycle.
Cheng et al (1996)	<ul style="list-style-type: none"> • Transitory Earnings have smaller marginal impact on security Returns. • The incremental information content of accounting Earnings decreases, and the incremental information content of CFO increases with a decrease in the permanence of Earnings.
Club (1995)	<ul style="list-style-type: none"> • Accounting Earnings data possesses information content beyond Cash Flow data indicating that unexpected working capital from operations and unexpected long-term accruals both have incremental information content beyond operating, investment and financing Cash Flows.

TABLE 1 (continued)

Authors	Results
Collins, Kothari and Rayburn (1987)	<ul style="list-style-type: none"> • Their study helps to explain the inverse relation between firm size and the strength of association between unexpected annual Earnings and contemporaneous security price changes. • Their empirical results showed that price-based Earnings would outperform univariate time series forecasts by a greater margin for larger firms than for smaller firms.
Collins and Kothari (1989)	<ul style="list-style-type: none"> • ERC increases in growth and/ or persistence and decreases in interests rates and risk. • They also demonstrated empirically that Earnings/ Returns relation varies with firm size, where size is a proxy for information environment differences.
Dechow (1994)	<ul style="list-style-type: none"> • She showed that over short measurement intervals Earnings are more strongly associated with Returns than Cash Flows. • The results indicate that the explanatory power of Cash Flows increases over long measurement intervals. • Earnings have a higher association with stock Returns than Cash Flows in firms experiencing large changes in their Working Capital requirements and their investment and financing activities. • Although accruals improve Earnings association with stock Returns, long-term accruals play a less important role in minimising the timing and matching problems of Cash Flows. • Earnings better reflects firm performance than CFO for firms in industries with long Operating Cycles.
Easton and Zmijewski (1989)	<ul style="list-style-type: none"> • Their results indicated a positive association between ERC and firm size. • ERCs are negatively correlated with systematic risk. • They provided evidence that ERCs vary cross-sectionally and in a predictable manner.
Easton and Harris (1991)	<ul style="list-style-type: none"> • The coefficients of levels and changes of Earnings are generally significantly different from zero. Both Earnings variables play a role in security valuation.
Easton et al (1992)	<ul style="list-style-type: none"> • The longer the interval over which Earnings are aggregated, the higher the cross-sectional correlation between Earnings and Returns.
Freeman (1987)	<ul style="list-style-type: none"> • Security prices of large firms reflect information about Earnings earlier than the prices of small firms. • The magnitude of abnormal Returns associated with good or bad news from a common class of signals (Earnings) is inversely related to firm size.
Freeman and Tse (1992)	<ul style="list-style-type: none"> • Present evidence that the marginal response of stock price to Unexpected Earnings declines as the absolute magnitude of Unexpected Earnings increases.
Hall et al (1994)	<ul style="list-style-type: none"> • Their results are consistent with the perception that Japanese investors utilize accounting information particularly Earnings, less in their pricing of companies than do US investors. • The increased associations derived with the inclusion of 1991 prices suggest that the current fall in prices is consistent with a Return to more emphasise on fundamental values.

TABLE 1 (continued)

Authors	Results
Kothari (1992)	<ul style="list-style-type: none"> The average and median explanatory power of firm-specific time-series regressions is higher when returns are regressed on the earnings deflated by price variable compared to the earnings change deflated by price variable. Price outperforms earnings as a deflator.
Livnat and Zarowin (1990)	<ul style="list-style-type: none"> The separation of Net Income into Operating Cash Flows and Accruals does not improve the relation with Returns. When Cash Flows are disaggregated the association with Returns improves substantially. Individual components of Cash Flows are differentially associated with security Returns.
Ohlson and Shroff (1992)	<ul style="list-style-type: none"> Given unpredictable returns, the Earnings levels variable correlates more with returns than the Earnings change variable if the levels variable has smaller sample variance. The Earnings levels variable is the best explanatory variable for Returns if neither Returns nor Earnings levels are predictable.
Pope and Walker (1999)	<ul style="list-style-type: none"> UK GAAP earnings are significantly more timely in the recognition of bad news than US GAAP earnings. UK firms recognize bad news faster than US firms, but they classify the bad news differently.
Rayburn (1986)	<ul style="list-style-type: none"> The results support the association of both operating Cash Flow and aggregate accruals with abnormal Returns. The results for the components of accruals are less consistent. All of the components of accruals are significant when a random walk process is assumed to generate the time series of each component.
Teets and Wasley (1996)	<ul style="list-style-type: none"> Using random samples of firms we find that the mean of the firm-specific coefficients is on average 13 times larger than the corresponding coefficient estimated with a pooled cross-sectional regression methodology. The average of the firm-specific coefficients is always larger than the corresponding Earnings response coefficients estimated from pooled time-series regressions.
Warfield and Wild (1992)	<ul style="list-style-type: none"> Revealed an inverse relation between Earnings explanatory power for Returns and the length of the reporting period. Future period Earnings are significantly related to Current Returns and are often of greater explanatory power for Current Returns compared with Current Earnings. Earnings explanatory power is substantially greater for companies whose Earnings measurements are predictably less sensitive to accounting recognition criteria.
Wilson (1986)	<ul style="list-style-type: none"> Cash and Total Accruals components of Earnings have incremental information content beyond Earnings themselves. Total Accruals components of Earnings has incremental information content beyond the Cash component.

2.4 The role of cash flows in the capital markets

Several researchers examined the association between earnings, cash flows and security returns. Ball and Brown (1968), Beaver and Landsman (1983) among others found that the association between security returns and operating earnings is higher than that between security returns and cash flows, where cash flows were defined as:

1. either net income + depreciation
2. working capital (earnings plus non-cash expenses/revenues).

Though the two financial variables (cash flows and working capital) were believed to be highly correlated, research does not support this view. Research, however, suggests that the use of working capital variable is inadequate in studying the properties of cash flows (Bernard and Stober, 1989, Wilson, 1987, Rayburn, 1986; Lev, 1989).

Empirical studies by Ball et al. (2003), Bartov, (2001), Livnat and Zarowin (1990), Charitou and Ketz (1991), Wilson (1986, 1987), Rayburn (1986), Bowen (1987), employed more refined cash flow measures, namely operating cash flows to examine the stock market reaction to accruals and cash flows measures. The results provided by these studies are inconclusive and the explanatory power of these statistical models is weak (i.e., very low R^2).

Table 1 presents a brief discussion of the major results of selected prior studies that relate to this issue. More specifically, the empirical evidence provided thus far regarding the quality of the accrual and cash flow measures has been mixed and inconclusive (Cheng and Yang, 2003, Bartov et al., 2001, Livnat and Zarowin; 1990). An early study by Wilson (1987) provided evidence that cash flows are valued more than current accruals in the marketplace. On the other hand, Bernard and Stober (1989), showed that accruals and cash flows have the same informativeness in explaining security returns, that is investors value equally cash flows and earnings in the capital markets. Bowen (1987) showed that accruals and cash flows are valued

differently in the marketplace. These results as well as results provided by Rayburn (1986) were inconclusive with regards to the role of accruals in explaining security returns.

Since prior studies provided inconclusive and mixed results regarding the usefulness of earnings and cash flows in the marketplace, some other researchers provided some explanation as to why financial markets or investors value cash flows and earnings differently. Under the quality of the earnings explanation, earnings are expected to have a smaller impact on stock prices than operating cash flows, because earnings represent only indirect link to expected cash flows (Neill et al, 1991). Earnings may also be manipulated by managers. Moreover, during a period of economic downturn the differential stock price reaction to accruals and cash flows are attributable to how well organizations anticipate and adjust to changing economic conditions. During recessionary periods, the market is expected to react favourably when management liquidates non-cash working capital, which would manifest itself as a preference for cash flow over short term accruals (Bernard and Stober, 1989). Stock markets are also expected to react more favourably to cash flows than accruals because high liquidity is a signal of a smaller likelihood of financial distress (Sharma and Iselin, 2003; Uhrig-Homgurg, 2005).

Furthermore, stock markets are expected to respond more favourably to operating cash flows than to accruals, because there is a belief that accruals are subject to arbitrary allocations and managerial manipulation. Earnings are manipulated because a) they are used in executive compensation contracts and b) there is a belief that investors pay more for a firm with a smoother income stream.

Indeed, in the past two decades there has been increased attention in cash flow reporting, since there exists evidence that earnings show the profitability and not the cash flow ability of the organization. In the mid-1980s and in early 1990s, standard setting bodies in the USA, Canada, UK, Australia and the International Accounting Standards Committee issued reporting

standards that require the Statement of Cash Flows as one of the three major financial statements.

Several researchers have examined the usefulness of cash flows in the capital markets, beyond the earnings information. In the mid-1980s, US studies by Rayburn (1986), Wilson (1986, 1987), Bowen et al. (1987), Bernard and Stober (1989), and Livnat and Zarowin (1990) provided evidence that operating cash flows are associated with security returns but provided limited support for the incremental information content of cash flows beyond earnings. Livnat and Zarowin (1990) and Bernard and Stober (1989) showed that the decomposition of earnings into operating cash flow and accruals does not improve the association with returns, although their finding of a differential return response to the components of operating cash flow suggests incremental information content for this disaggregated operating cash flow data beyond accounting earnings. In the UK, a study by Board and Day (1989) did not find incremental information content for operating cash flow beyond accounting earnings.

While early studies on the value relevance of cash flows provided inconclusive results, more recent research in the past decade has further extended the variety of approaches to analyzing the relative information content of earnings and cash flow data and has provided further evidence in favour of the incremental information content of cash flows than the earlier research considered above. Like the earlier research, most of the more recent research might be regarded as concerned with the contemporaneous relationship between annual accounting data and annual security returns (Ali 1994; Ali and Pope 1995; Cheng et al. 1996; Clubb 1995; McLeay et al., 1997; Garrod and Hadi 1998; Charitou 1997; Charitou et al. 2000; Pfeiffer et al., 1998, 1999; Green 1999; Ball et al. 2000, 2003; Bartov et al. 2001), but there has been a greater emphasis on addressing more directly further methodological advancements. The modelling of contextual factors possibly affecting the incremental information content of cash flows, improved measurement of accounting variables and an interest in the possible non-

contemporaneous relationship between security returns and cash flows have had an increasing effect on the design of empirical research. The discussion below emphasizes research concerned with the contemporaneous relationship between annual accounting data and annual security returns, before considering other research findings focusing on long return windows and possible non-contemporaneous relationships between return and accounting data.

As far as the contemporaneous relationship between annual returns and cash flows is concerned, empirical evidence in the 1990s by Ali (1994), Ali and Pope (1995), and Cheng et al. (1996) provided positive evidence of the incremental information content of operating cash flows beyond earnings using more elaborate cross-sectional models of the relationship between security returns and earnings/cash flows than previously employed. Freeman and Tse (1992), Ali (1994) and Ali and Pope (1995) extended prior cash flow research by estimating non-linear models of the relationship between abnormal returns and unexpected earnings, unexpected funds flow and unexpected operating cash flow.

In these studies the marginal security return response to accounting innovations declines with the absolute size of the innovation. The indicator variable approach of Ali (1994) based on US data provides evidence of an earnings response coefficient in excess of 2.0 for firms with below median absolute earnings changes and statistically significant additional positive security return response to operating cash flows (CFO) for firms with below median absolute changes in CFO. There is no evidence of incremental information content for cash flows in the simple linear model, possibly due to the effect of extreme cash flow realisations which, according to Ali's findings, have no incremental information content.

Regarding the empirical evidence of the UK study by Ali and Pope (1995), their results show that there exists incremental information content for cash flow from operations in a pooled analysis with time varying coefficients. Cheng et al (1996) use a dummy variable approach to

estimate a non-linear contextual model of a different form where the security return response to unexpected operating cash flow is permitted to vary with the absolute size of accounting earnings changes. Their study provided evidence of an earnings response coefficient greater than 4.0 for firms with below median absolute changes in earnings, together with evidence that CFO has a positive additional impact on security returns beyond earnings both for the sample as a whole and particularly for firms with above median absolute earnings changes.

The use of both levels and changes of earnings and cash flows as explanatory variables helps to explain the higher ERCs reported by Cheng et al and the strength of their findings in relation to the incremental information content for cash flow beyond earnings even for the 'non-contextual' simple linear model. An interesting feature of this study is the strength of their findings of incremental information content in the simple non-contextual model. These results support incremental information content even for a random walk model for cash flow but the results are stronger when both levels and changes are used and clearly indicate the greater importance of the cash flow level variable over the change variable as an explanatory variable for returns.

A common feature in the aforementioned studies is the incorporation of cross-sectional differences in earnings and cash flow persistence into their analysis by estimating a non-linear model where the marginal security return response is permitted to vary but where, nevertheless, earnings and cash flow variables are measured in a standardised way across sample observations i.e. either as the first difference of the variable or as a combination of the level and the first difference of the variable.

By contrast, following Rayburn (1986), the UK studies by Clubb (1995) and McLeay et al (1996) use firm-specific forecast models to estimate innovations in accounting variables. More specifically, the study by Clubb (1995) uses the dividend valuation model to motivate a time

series analysis of the incremental information content of accounting earnings and operating, investment and financing cash flows, whereas the study by McLeay (1995) focuses on the relative information content of earnings and operating cash flows using both time series and pooled cross-sectional approaches. Clubb (1995) finds support incremental information content of operating, investment and financing cash flows beyond earnings but cannot reject the hypothesis that operating, financing and investment cash flows (defined to sum to net equity dividends as change in cash are included as part of investment) provide no incremental information content beyond both earnings and dividends. McLeay et al (1972), using a similar dataset to Ali and Pope (1995), find support for incremental information content of operating cash flow, obtaining a similar R^2 for the incremental information model to results reported by Ali and Pope.

While the use of firm-specific forecast models to estimate earnings and cash flow innovations may have advantages over an approach that uses a standard measurement approach for all firm-year accounting variable observations, measurement error in the estimation of the forecast model is likely to affect the findings. The relatively low earnings response coefficients reported by McLeay et al (less than 1.0 compared with approximately 2.0 in Ali and Pope, 1995) suggests that measurement error may have affected the reported regression coefficients.

Furthermore, Biddle et al (1995) have suggested that industry analysis may be the most appropriate way to accommodate cross-sectional differences between firms when examining incremental information content. While they do not report earnings and cash flow response coefficients, they find that cash flows provide incremental information content beyond net income in 22 (11) industries for one-lag (random walk) estimation, out of a total of 40 industries, in contrast to the mixed findings in the earlier studies on incremental information content of cash flows.

In addition to the aforementioned contemporaneous analysis of the value relevance of cash flows, some of the more recent research examined non-contemporaneous relationships between security returns and earnings/cash flow data. This kind of empirical research emphasises the potential usefulness of cash flow data in predicting future returns, although work adopting the long return interval approach (Dechow 1994) first used by Easton et al (1992) to analyze earnings data alone, incorporates the possibility of earnings/cash flow data having predictive and/or lagged associations with security returns in addition to a contemporaneous relationship. Chan et al. (1991) find that cash flow yield (where cash flow is the traditional definition, earnings plus depreciation) provides incremental information content for future security returns beyond earnings yield, book-to-market and log of market capitalisation, using Japanese data over the period 1971-88. They suggest that the highly significant positive coefficient for cash flow yield (together with book-to-market) and the counter-intuitive negative coefficient for earnings yield may be due to use of conservative depreciation policies by Japanese companies to reduce tax. Interestingly, Sloan (1996) using US data for the period 1962-91 provides evidence that accruals have incremental information content for security returns beyond earnings yield, book-to-market and log of market capitalisation, implying that cash flow from operation is significantly positively related to future returns in a US setting.

More generally, Sloan presents extensive findings suggesting that security returns and investor earnings forecasts do not immediately reflect the higher persistence of the cash flow component of earnings over the accruals component. In the UK, evidence by Charitou et al. (2000) also suggests a significantly positive relationship between security returns and previous year cash flow from operations after controlling for contemporaneous earnings and cash flow, previous year earnings and previous year market-to-book and equity market value variables. In summary, there is growing evidence that cash flow data can be useful in predicting future

security returns, a result which possibly indicates a degree of market inefficiency in relation to the reflection by security prices of the relative persistence of cash flow and accrual components of earnings.

The study by Dechow (1994) based on US data and Charitou et al. (2000) based on UK data provide evidence based on US and UK data respectively that earnings and cash flow measures become more closely correlated with share returns as the return interval is expanded and accounting variables are aggregated over periods up to four years. The study by Dechow (1994) focuses on the relative information content of earnings and two cash flow measures, cash flow from operations and change in cash balance, and finds that, while the relative superiority of earnings over cash flow narrows as the return interval is expanded, earnings are superior relative to cash flows over all intervals.

In addition to broadly corroborating Dechow's findings based on UK data, Charitou et al. (2000) findings suggest that the incremental information content of operating cash flow a range of operating, investing and financing cash flows beyond earnings persists over long intervals. The use of long-return intervals and earnings/cash flows aggregated over several years may result in an improved association vis-à-vis annual intervals either if security prices anticipate future accounting numbers and/or if accounting numbers anticipate future returns. The analysis of Dechow (1994) emphasizes the confirmatory role of earnings and cash flow numbers, the explanatory power of both accounting earnings data and cash flow data for security returns increasing due to reduced measurement error resulting from accounting policy choices in the case of earnings and reduced measurement error due to omission of current accruals in the case of cash flow data.

Furthermore, the UK evidence of continued incremental information content of cash flows beyond earnings as the return interval increases may suggest that such measurement error in accrual earnings is still substantial over longer horizons and that cash flow data is required to provide an

accurate picture of actual economic outcomes. It is also possible, however, that the expansion of the return interval (with simultaneous intertemporal aggregation of accounting numbers) results in incremental information content for cash flows over earnings because of the additional predictive power of annual cash flow data in relation to future returns, as suggested by the findings of Sloan (1996).

Furthermore, a more recent study by Bartov, et al. (2001) examined the value relevance of cash flows beyond earnings in five countries, namely, USA, UK, Germany, Japan and Canada. Their results indicated that cash flows and earnings play a very important role in the capital markets. Specifically, their results showed that earnings developed in the three Anglo-Saxon countries, namely USA, UK and Canada, where capital is traditionally raised in public markets, to have greater explanatory power for stock returns than operating cash flows. On the other hand, in the two common law countries, Germany and Japan, where capital is traditionally raised from private sources, earnings are generally not superior to operating cash flows for equity valuation. As it was expected, the results of this study showed that in all countries examined, earnings have incremental information content over cash flows in explaining security returns. In summary, the findings of this study provide the following contributions. First, prior US findings are generalized by showing that earnings are more important than cash flows for equity valuation in other Anglo-Saxon countries. Second, results showed that the superiority of earnings over cash flows is not universal but it depends on the national reporting regime and on the institutional factors.

In addition to the aforementioned earnings and cash flow variables, researchers used additional explanatory variables to explain security returns, among those, growth (book to market), size and risk (Banz, 1981; Fama and French, 1992; Jaffe et al., 1989; Pae et al., 2005; Ball et al., 2001, 2003; Chambers, 2004; Chan et al., 2006; among others). More specifically, Banz (1981) documents a strong negative relation between average return and size. Basu (1983)

shows that the earnings/price ratio can be used to explain cross sectional differences of average returns on US stocks in tests that also include size and market beta. Chen et al. (1992) found that the book to market ratio and cash flow are positively associated with security returns in Japan. Fama and French (1992) show that size and book to market ratio provide a simple and powerful characterization of the cross section of average returns for the 1963-90 period in the US. Black, Jensen and Scholes (1972) and Fama and MacBeth (1973) find that there is a positive simple relation between average returns and beta.

A detailed discussion of the empirical studies that employed earnings, cash flows and other contextual factors such as measurement interval, size, growth, operating cycle etc, follows.

2.5 The use of contextual factors in improving the association between financial information and security returns.

Since prior studies of the association of earnings with security returns provided conclusive but relatively weak relationship, researchers employed additional contextual factors in order to strengthen the relationship between financial information and security returns. The major contextual factors employed in the capital markets literature are:

- i. Measurement interval
- ii. Earnings persistence
- iii. Firm's growth
- iv. Firm's size
- v. Operating cycle
- vi. Aggregate accruals

Table 2 summarizes the major contextual factors employed in prior selected studies.

Different types of methodological issues employed in each study are also presented. A discussion of the major contextual factors/ issues related to these studies follows.

2.5.1 The effect of the measurement interval

Capital market studies use both short (e.g. 2 day) and long windows extended from 60 days to several years. A short window is preferable if a large portion of uncertainty about the firm's performance is resolved at the time of the annual reports release. The justification for using short windows is that they reduce the effects of confounding information. On the other hand, a long window is preferable when the uncertainty about the firm's performance is resolved gradually over an extended period of time (Cho and Jung, 1991). Given that the primary interest of this paper is the value relevance of the released information, one of its important features will be a focus on the effect of long returns intervals (greater than one year) where the timing of information dissemination is less of an issue (Harris et al. 1994).

Most prior studies investigated the information content of accounting earnings over short return intervals (Easton and Harris, 1991). Very few studies used long windows to examine the role of earnings in the marketplace (Easton et al., 1992; Warfield and Wild, 1992) and only a couple of studies extended the long return interval analysis for cash flows (Dechow, 1994; Charitou, 1997). Easton et al. (1992) and Warfield and Wild (1992) examined only the association of earnings with security returns and showed that this association improves over longer measurement intervals. Easton et al. (1992) showed that the R^2 is increased from 5% for one year interval to 63% for the 10 year interval. Finally, Hall et al. (1994) using Japanese data showed that the R^2 is improved over long return intervals but the explanatory power is much lower compared to the US data. See also Table 2 for a detailed presentation of the major characteristics of these studies.

As far as the value relevance of cash flows in longer windows is concerned, Dechow (1994) and Charitou (1997) did not consider multivariate analysis of cash flows or their

incremental information beyond earnings, but used only univariate regression models. Dechow (1994) and Charitou (1997) show that there is a relative increase in the explanatory power of operating measurement intervals. More specifically Dechow (1994) shows that the ratio of $R^2_{CFO} / R^2_{Earnings}$ increases from 0.003 for quarterly data to 0.27 for the four year measurement interval³. Charitou (1997) shows similar results, with $R^2_{CFO} / R^2_{Earnings}$ increase from 0.06 for one year to 0.26 for the 5-year measurement interval.

2.5.2 The effect of earnings persistence

Earnings persistence studies consistently report that earnings persistence is significantly positively associated with ERC (Easton and Zmijewski, 1989; Donnelly and Walker, 1995; Ali and Zarowin, 1992; Chambers, 2004). Cheng et al. (1996) extended prior studies on this topic and added cash flow variables in their models. They found that the incremental information content of cash flow from operations(CFO) should increase with a decrease in the permanence of earnings. Furthermore, Ali (1994) using non-linear models concluded that earnings, cash flows and working capital from operations(WCFO) have incremental information, which increases the lower are the absolute changes in earnings, cash flows and WCFO respectively. Finally, Ali and Zarowin (1992) show that the more transitory the previous period's earnings are, the greater the increase in the ERC and the expected incremental explanatory power from inclusion of the level variable. According to Cho and Chung (1991) the persistence measure used in those studies has 3 limitations: first, although persistence is changing over time, a constant parameter assumption is made which is problematic, especially when estimations are based on annual data for several year time series. Second, a measurement error problem exists, from using time-series reported earnings. Easton and Zmijewski (1989) use revision coefficient avoiding to some extent the

³ Where CFO is cash flow from operations

latter problem. The third limitation is that persistence as measured by the time series of earnings is a crude proxy for the construct because it contains little economic content.

Researchers also extended prior studies in order to examine the value relevance of the permanent and transitory earnings. Cheng et al (1996), Ali (1994), Ali and Zarowin (1992) and Easton and Zmijewski (1989) among others examine the impact of permanent and transitory earnings on the relations between returns and earnings or between returns and cash flows. Ali and Zarowin (1992) concluded that for firms with permanent earnings in the previous period, when the earnings level variable is included in the model, the incremental explanatory power and the increase in Earnings Response Coefficient (ERC) are small. Cheng et al. (1996) investigated whether the incremental information content of cash flows increases when earnings are transitory. Transitory earnings have smaller marginal impact on security returns. Moreover, their results showed that the incremental information content of accounting earnings decreases, and the incremental information content of cash flows increases with a decrease in the permanence of earnings. See also Table 2 for a detailed presentation of the major characteristics of these studies.

2.5.3 The effect of firm's growth

Collins and Kothari (1989) note that future earnings are affected from current growth opportunities, and therefore the earnings response coefficients (ERC) are affected as well. They included in their reverse regressions the Market Value to Book Value ratio (as a measure of growth) and concluded that it has positive incremental information content beyond persistence. However, Cho and Jung (1991) argue that time series analysis cannot reflect current growth opportunities, because they are not " fully and accurately captured by time series persistence estimates " (p. 85).

Chan et al. (1991) also used a measure of growth (Book to Market Value ratio) in their

Seemingly Unrelated Model (SUR), together with earnings cash flow yield, and size (measured by log of MV of Equity). Their findings suggest that BV/MV is the most important variable of the four used, while cash flow yield has positive incremental information content. However, cash (flow) yield variable was defined as earnings plus depreciation.

Finally, Fama and French (1992) also support the conclusion that among the variables considered in their study (size, leverage, earnings price ratios, market β) book to market equity is consistently the most powerful for explaining the cross section of average stock returns. In addition Fama and French suggest that the combination of size and book to market equity absorbs the apparent roles of leverage and E/P in average stock returns. However book to market equity does not replace size in explaining average returns. Table 2 also presents detailed methodological issues associated with prior studies, including contextual factors that relate to growth.

2.5.4 The effect of firm's size

According to Freeman (1987) there are reasons to expect private information production to increase with firm size. Regulatory bodies in many countries distinguish between large and small firms, and demand more Flow Statement releases with more information from larger firms. In addition, the financial press and financial analysts have incentives to focus on large firms because they are more widely held and attract the interest of more readers and investors. Another reasonable explanation is that large firms make more transactions so there are more to report about them.

Of course, larger corporations have very complicated Flow Statement and in general their structure and operations differ dramatically compared to smaller ones. So the cost of analysing their financial data becomes very expensive. For that reason many large firms maintain public

relations departments staffed by professionals - analysts to answer telephone and written inquiries. According to Freeman (1987), if marginal search costs increase with firm size, but at a lower rate than marginal trading profits, a large firm's securities are less likely to be mispriced than a small firm's.

Many studies examine the relation between firm size and accounting measures, especially earnings. Easton and Zmijewski (1989) investigated the correlation between firm size and ERC. The coefficient was not significant in every case they examined. Additionally, Donnelly and Walker (1995) show positive correlation of firm size with earnings changes, and to a lesser extent with earnings levels. In contrast, Freeman (1986) concluded that the impact of abnormal returns associated with accounting earnings is negatively related to firm size. In the next section (Hypothesis 6) a possible explanation is given, for the difference in results of the above studies. Finally, Fama and French (1992) find that size (ln of market equity) helps explain the cross-section of average stock returns. This reliable negative relation persists no matter which other explanatory variables are in the regressions. Although part of the size effect in the univariate regressions is due to the fact that the small market equity stocks are likely to have high book to market ratios, Fama and French argue that we should not exaggerate the links between size and book to market equity. The correlation between these two variables is not extreme ($r=-0.26$) and the average slopes in the bivariate regressions show that are both needed to explain the cross section on average returns.

Regarding the size effect on cash flows/returns relation, the only study that examined this issue is the one by Bernard and Stober (1989). Their results did not provide evidence that information about unexpected cash flows was more likely to be impounded in market prices for small firms than for large firms. Table 2 presents a summary of the major characteristics of prior selected studies that employed firm size.

2.5.5 The effect of operating cycle length

Dechow (1994) and Charitou (1997) using US and UK data respectively, investigated how the size of firm's operating cycle might affect the association between returns and cash flows. Dechow (1994) and Charitou (1997) found that in industries where the operating cycle is long, securities returns are associated more with earnings than with cash flows because working capital requirements are more volatile. Charitou (1997) found that when the operating cycle is increased, the R^2 adj. of earnings increases from 15.8% to 23.7%, while the R^2 adj. of cash flows is decreased from 3.5% to 1.1%. Dechow (1994) shows that there is a negative correlation ($r = -0.483$) between the length of operating cycle and the R^2 from the cash flows regressions. However no obvious decline in the R^2 of earnings was observed as the length of the operating cycle increases. This suggests that accruals play a relatively more important role for firms in industries with long operating cycles.

Both studies investigated the information content of earnings and cash flows separately, by performing univariate regression models only. This thesis extends this work and also tests whether the incremental information of cash flows is greater in industries with smaller operating cycle by performing multivariate regression models.

2.5.6 The effect of aggregate accruals

When accruals are small in magnitude, cash flows have a higher association with security returns, because their timing and matching problems are minimized. On the other hand, cash flows' timing and matching problems are increased when accruals are large and when firms are not in a steady state. Dechow (1994) considers an example for a ship building firm with long-term contracts, and in which earnings will reflect better the contract's value and the firm's

performance. Accrual process is most important for firms with large changes in their non cash accounts balances, for example big construction firms where their annual cash flows are very volatile (Dechow, 1994).

Dechow (1994) and Charitou (1997) showed that cash flows play a more important role in the market place, the smaller the absolute value of accruals. Dechow used quarterly, annually and 4-year periods while Charitou used only yearly data. Both studies test for possible association of cash flows with security returns, and conclude that while R^2 adj. of firms with high accruals was below 1%, the R^2 adjusted of firms with small accruals exceeded 15 %. Concerning the association of earnings with security returns, the two studies have different results: Dechow shows that the R^2 adj. of firms with high accruals is 20.47% while the R^2 adj. of firms with low accruals is only 15.8%. On the other hand Charitou shows that the R^2 adj. of earnings decreases the higher the absolute value of accruals (the R^2 adj. is 17.5% for firms with low accruals and only 11.5% for firms with high accruals). Again none of the two studies investigated the incremental information content of cash flows beyond earnings. This hypothesis will be tested in this study by performing a multivariate regression model.

2.6 Summary of the critical review of the value relevance literature

In this chapter I critically evaluated the literature that relates to the value relevance of earnings and cash flows. Specifically, I provided an in depth discussion of the significance of earnings and cash flows in the capital markets and I also critically evaluated the existing value relevance empirical studies that were undertaken worldwide. In summary, empirical research thus far provided evidence to support that both earnings and cash flows are valued in the marketplace, but earnings do dominate cash flows in the capital markets. On the other hand earnings have been criticized because it was shown in prior studies that they are manipulated by managers.

Moreover, prior evidence showed that the explanatory power of earnings (as measured by the R^2) has been relatively low. As far as the evidence on the value relevance of cash flows beyond earnings, it has also been shown inconclusive. These inconclusive results motivated researchers to examine further this issue by investigating in more depth the circumstances under which earnings and cash flows can play a more important role in the marketplace. Specifically, researchers examined the effect of the measurement interval on the value relevance of earnings and cash flows, the value relevance of cash flows when earnings are transitory, and the role of earnings and cash flows after controlling for growth, size, operating cycle and accruals. Even though researchers found that the value relevance of earnings and cash flows improves after considering for the aforementioned factors, these studies were limited in the sense that researchers examined mainly one of those factors at a time in a single capital market, and mainly in the US market.

Based on the critical discussion and analysis presented in this chapter, it is concluded that this research study differs from prior studies in the following respects. First, it examines not only the value relevance of operating cash flows beyond earnings, but it also examines the role of cash flows in the capital markets after considering the industrial effects in both Anglo-Saxon and code law countries on the relative usefulness of operating earnings and cash flows in explaining security returns. Second, it examines the value relevance of earnings and cash flows when the measurement interval increases. Third, the above major research questions are examined empirically using data from UK and USA (Anglo-Saxon countries) and France (a code law country) in order to determine whether the valuation role of financial information differs in these countries. Fourth, this study examines comparatively the valuation of financial information such as earnings and cash flows, over longer measurement intervals for the UK, USA and France. Thus far, no other study has examined the above issues using comparative statistics for the U.K,

US and France. Since there are several financial reporting, economic and social differences between the above countries, it is expected that this study will provide new insight regarding the effect, if any of these differences, on the value relevance of earnings and cash flows in these countries.

In the next section, I go a step further by critically evaluating the international financial reporting literature and especially the financial reporting systems in Anglo-Saxon and code law countries. Specifically, I provide comparative analysis of the financial reporting systems in two Anglo-Saxon countries, namely the UK and the USA, and in one code law country, namely, France.

CHAPTER III

CRITICAL REVIEW OF THE INTERNATIONAL FINANCIAL REPORTING LITERATURE

3.1 Introduction

This chapter critically evaluates the international financial reporting literature. Specifically, it provides an in depth discussion of the comparativeness of the financial reporting systems in Anglo-Saxon countries (UK and USA) and Code law countries (France). It also evaluates the different financial reporting systems as they relate to the standards issued in different countries (the UK Accounting Standards Board statement entitled 'Cash flows Statements,' FRS #1; the US reporting Standard #95). In addition, it discusses existing empirical studies that were undertaken worldwide which examine the association between earnings, cash flows and security returns.

More specifically, the following sub-sections follow:

1. International classification of financial reporting systems;
2. Financial reporting in France, UK, USA:
 - a. Financial reporting in France;
 - b. Financial reporting in UK;
 - c. Financial reporting in the USA.
3. Comparative analysis of the financial reporting systems in the UK, USA and France;
4. Differences in the value relevance of earnings and cash flows between Anglo-Saxon

countries (UK, USA) and France;

5. Financial reporting in the UK: the statement of cash flows (Financial Reporting Standard No. 1).

A discussion and critical evaluation of the above issues follows.

3.2.1 International classification of financial reporting systems

There are major international differences in financial reporting practices. Some countries have a legal system which relies upon a limited amount of statute law, which is then interpreted by courts, which build up large amounts of case law to supplement the statutes. Such a 'common law' system was formed in England primarily by post-Conquest judges acting on the king's behalf. It is less abstract than codified law; a common law rule seeks to provide an answer to a specific case rather than to formulate a general rule for the future. Although this common law system originated in England, it may be found in similar forms in many countries influenced by England. Thus, the federal law of the United States, the laws of Ireland, Australia and so on, are to a greater or lesser extent modelled on English common law. This naturally influences company law, which traditionally does not prescribe a large number of detailed rules to cover the behaviour of companies and how they should publish their financial statements. To a large extent, financial reporting within such a context is not dependent upon law (Lee et al. 2005, Nobes and Parker, 2004; Weetman et al. 2005).

Other countries have a system of law which is based on the Roman *jus civile*. In these countries, the rules are linked to ideas of justice and morality. The word 'codified' may be associated with such a system. This difference has the important effect that company law or commercial codes need to establish rules in detail for financial reporting. Both the nature of regulation and the type of detailed rules to be found in a country are affected.

Moreover, the prevalent type of business organization and ownership also differ. In France and Italy, capital provided by the state or by banks is very significant, as are small family business. In code-law countries the banks or the state will, in many cases, nominate directors and thus be able to obtain information and affect decisions. If this is the case, the need for published information is less clear. This also applies to audit, because it is designed to check up on the managers in cases where the owners are 'outsiders' (Haskins et al. 2000; Weetman et al. 2005).

Although it is increasingly the case that shares in common-law countries are held by institutional investors rather than by individual shareholders, the increased importance of institutional investors is perhaps a reinforcement for the following hypothesis: "in countries with a widespread ownership of companies by shareholders who do not have access to internal information there will be a pressure for disclosure, audit and «fair» information" (Ball et al, 2000, p. 3). Institutional investors hold larger blocks of shares and may be better organized than private shareholders. So, they should increase this pressure, although they may also be able to successfully press for more detailed information than it is generally available to public.

In other words, common-law countries have evolved the presumption that contracting occurs between parties who are unrelated. There is no presumed contact between a company's manager and its investors. In contrast, contracting in code-law countries tends to be conducted by a small number of representative groups, such as major banks. This system requires close working relations between contracting parties. Common-law facilitates large, open, public debt markets in which long-term debt is supplied by parties who are unrelated between them and hence rely on public information. In code-law countries, debt is provided primarily by intermediaries which have close bonds with the corporate borrower and receive large private information.

The similarities of company financial reporting in the major Anglo-Saxon countries are

well known and, indeed, the differences between these countries must be emphasized (Haskins et al., 2000; Walton et al. 2003; Nobes and Parker, 2004, Lee et al. 2005). There are several ways in which company financial reporting can be regulated. Three limiting and ideal cases are: through the ‘market’, the ‘state’ and the ‘community’. If the process is left entirely to market forces each company chooses its own rules, influenced only by pressures from the capital market. At another extreme the whole process can be in the hands of the ‘state’, an organ of which decrees which practices to be followed and provides an enforcement mechanism. The third ideal case is the emergence of rules through the ‘spontaneous solidarity’ of the community.

Within these three extremes, Puxty et al. (1987) usefully distinguish what they and others term ‘liberalism’, ‘associationism’, ‘corporatism’ and ‘legalism’.

At one extreme is liberalism, whereby regulation is provided exclusively by the discipline of the market principles, while companies provide information only if it is demanded commercially. At the other extreme is legalism, which relies upon the unreserved application of state principles. Financial reporting practices are expected to follow the letter of the law, which is enforced by the state’s monopoly of the means of coercion.

Within these two extremes are associationism and corporatism, both of which combine

liberalism and legalism with a small dose of community influence. In associationism, regulation is accomplished through the development of the organisations that are formed to represent and advance the interests of their members. These members form part of the community, but do not represent it as a whole. Corporatism involves a greater reliance upon the state principle of hierarchical control. The state does not simply license the existence of organized interest groups, but incorporates them into its own centralized, hierarchical system of regulation. The basic difference between corporatism and associationism is the extent to which the state 'leans' on interest groupings to achieve public as contrasted with private purposes.

In the United Kingdom, company legislation has long been the prime mode of accounting regulation. The legislation has generally owed much to the prior initiative of the accountancy profession. In the United States financial reporting was almost unregulated until the establishment of the Securities and Exchange Commission in the 1930s. Throughout its existence the SEC has generally limited itself to a supervisory role, but it has not hesitated, on occasion, to intervene directly in the standard-setting process.

Tables 3-6 provide information regarding a) the financial reporting and principles in these countries (Table 3); b) the financial reporting requirements in the USA, the UK and France (Table 6); c) the financial reporting standards in the UK, the USA and France (Table 5); and d) the major differences and expectations between Anglo-Saxon and code law countries (Table 4). A presentation and critical analysis of each of the major issues presented in the aforementioned tables is shown in the sections that follow.

Table 3**Financial Reporting Requirements and Principles in France, the UK and the USA**

Country	Accounting Requirements	Accounting Principles
France	Format Balance Sheet and Format Income Statement Notes Directors Report	Matching Consistency Disclosure of Assets and Equities Prudence Going Concern
UK	Balance Sheet Profit and Loss Cash Flow Statement for large firms Notes Directors Report Auditors Report Statement of total recognised gains and losses In the case of a parent or holding company a Consolidated profit and Loss and its own Balance Sheet	Going Concern Consistency Prudence Matching Separate valuation of individual
USA	Balance Sheet Income Statement Statement of Cash Flow 3 year information for Income Statement A statement of changes in Stockholders Equity Statement of Retained Earnings Notes to Financial Statement	Going Concern Consistency Prudence Matching Separate valuation of individual

3.3 Financial reporting in France, the UK and the USA

The three countries to be examined in the present study are the UK, the USA and France. The UK was selected because there is a controversy in the UK financial reporting literature regarding the value relevance of earnings and cash flows. UK studies provided inconclusive results in the past regarding the information content of earnings and cash flows. As far as the USA is concerned, it was selected to be used as a benchmark because the majority of research undertaken thus far examined US firms. However, USA studies examined only certain issues that relate to the value relevance of earnings and cash flows and the present study will provide a comprehensive analysis regarding the value relevance of financial information. As far as France is concerned, this country was selected because, contrary to the common law system followed in the UK and the USA, the French financial reporting system is based on code law. Preliminary evidence in the literature thus far, indicates that the value relevance of earnings and cash flows depends on whether the firms examined are under a common law or under a code law system. Thus far, studies have not examined empirically these issues.

A discussion of the financial reporting systems in the three countries (France, the UK, and the USA) that are examined in the present study, follows.

3.3.1 Financial Reporting in France

French accounting was introduced as a compulsory aspect of French business by *Ordonnance* of Colbert in 1673. This law, also called Savary law, was incorporated in the Commercial code of 1807 as part of the reorganization of French laws into codes during the period of rule of Napoleon. Company law was further reformed in 1867 covering matters which included the creation of *Societe Anonyme* as a form of business organization. It also provided for a form of auditing for this type of corporation (Weetman et al. 2005; Nobes and Parker, 2004).

The development of financial reporting practice in France has taken place largely within a political setting of a republic operating as a democracy. Swings in political power within that democracy may have slowed the pace of change in financial reporting practice compared with that of some other member states of the EU. On the other hand, the relative freedom of choice in the preparation of group accounts has provided new opportunities for flexibility of practice and opened financial reporting thinking to new concepts and practices. French financial reporting practice is based on a tradition of a code set by law. Tax law has developed separately from accounting law, but has been highly influential on the choice of financial reporting practice within the accounting law. Being a founder member of the EU gave an opportunity for France to influence the financial reporting practice of individual companies, through the Fourth Directive. France was in turn itself influenced, in the widespread adoption of consolidated accounting, by the Seventh Directive.

Comparing the French financial reporting with the Anglo-Saxon financial reporting, it is observed that the French reporting differs in a number of ways as a result of the approaches taken toward financial reporting standardization and outcomes achieved with the national accounting code or general accounting plan, namely the Plan Comptable General (PCG). The PCG is at the heart of financial reporting and accounting. It is issued under the authority of the French national accounting council (CNC). The code is revised at relatively infrequent intervals with amendments and additions occurring more frequently. There are two central objectives of the PCG: standardizing the organization of the accounting system of the enterprise and standardizing the presentation of financial results and position. Taken together, these ensure that the accounting records are maintained in a form which permits production of the required form of financial statements (Walton et al. 2003; Haskins et al. 2000; Nobes and Parker, 2004; Weetman et al., 2005).

Empirical studies classified France as a uniform system where accounting was seen as a means of governmental control. Nobes and Parker (2004) classified the French accounting system as tax based and macro-uniform, grouped with Italy, Belgium and Spain. Moreover, France was classified with the main body of European countries on the basis of measurement but with Belgium, Italy and Spain on the basis of disclosure.

The financial reporting in France is characterized by marginal professionalism, strong uniformity, strong conservatism and marginal secrecy. The political and legal institutions provide a basis of statutory control for financial reporting within accounting. Uniformity is influenced by the Fourth and Seventh Directives, but it is particularly strong in relation to the application of the chart of accounts. As far as conservatism is concerned evidence shows that the French accounting practice is placed at the highly conservative end of a spectrum, clustered with Japan and with other more developed Latin American countries. Conservatism is seen in the financial reporting treatment of provisions, long term contracts, inventories, asset valuation and contingencies and is influenced by the interaction of accounting and tax law. As far as secrecy is concerned, it is less prevalent in French financial reporting practice compared with some other EU countries, and there are extensive disclosures required by regulation (Nobes and Parker, 2004; Weetman et al. 2005; Walton et al. 2003).

As far as the relationship between company and tax law is concerned, the accounting law in France has been shaped by fiscal policy as enacted in tax law. Tax law has been concentrated on the construction of the balance sheet to ensure that the recording of transactions is carried out without the exercise of discretion over matters such as end-of-period adjustments. There is a general rule that expenses are tax deductible only if treated as expenses in the annual financial reports.

As far as the French capital markets are concerned, relatively few listed French firms

have widely dispersed shareholdings. Historically, French firms have not generally used the stock market as a source of financing, but in recent years there has been an increase in new equity financing. Firm growth and capital gains are the major factors taken into consideration by French investors in firm valuation. In contrast, French investors have a conservative view of expectations from dividends.

Concerning the influence of EU on French financial reporting, the Fourth directive reflects the French practice as contained in the Plan Comptable General (PCG) and reflects in particular the preference for financial statement formats. Implementation of the Fourth Directive required a major revision of the PCG in 1982 but this had the effect of confirming the uniformity of presentation in the firm's financial statements. A recent addition to the Fourth directive was the requirement for the true and fair view, translated into French as *image fidele*. This was dealt with in a manner similar to that of Germany in declaring that the true and fair view is established by reading the balance sheet, profit and loss account and notes taken together. Uniformity in the financial statements was thus preserved in the context of potential flexibility in the notes to the financial statements (Ball et al., 2000; Weetman, 2005; Walton et al. 2003; Nobes and Parker, 2004).

3.3.2 Financial reporting in the UK

Contrary to the financial reporting in France, the financial reporting practice in the UK has a strong tradition of professionalism. Statute law and financial reporting standards set general bounds on requirements but the professional accountant determines the detail of practice. The accounting profession is well established and there is a relatively wide requirement for audit of company accounts. Tax law has developed separately from accounting law and there is no requirement that accounting profit must be calculated under fiscal rules to be an acceptable base

for taxable profit. Membership of the EU, and the adoption of the Fourth and Seventh Directives, brought more specific requirements in the shape of accounting formats not hitherto known. Group accounting, and in particular consolidated accounting, was well established from 1948 onwards. Company law concentrates primarily on protection of shareholders and creditors. Other sources of authority indicate a concern with wider stake-holders. From time to time there have been concerns to ensure that the needs of employees are addressed and that the public interest is taken into account. This depends to some extent on the political views of the government. The current approach to standard setting places particularly strong emphasis on the needs of users, although there is no clear statement of their needs (Nobes and Parker, 2004; Weetman et al., 2005; Walton et al. 2003, Lee et al. 2005).

Using the scores developed by Hofstede (1984), Gray's (1988) method of analysis may be used to predict that the financial reporting system in the U.K will be characterized by strong professionalism, strong flexibility, strong optimism and strong transparency. The profession has a long history of development in the U.K and has traditionally operated in a framework where statutory control is limited to prescribing minimum standards only. Flexibility has been consistent with this professional approach, uniformity in matters such as presentation of formats being a relatively new feature caused by implementation of directives. Optimism, rather than conservatism, is seen in the use of alternative valuation rules to historical cost accounting. Transparency is seen in the extensive disclosures required of companies by way of footnotes to major financial statements (Weetman et al., 2005, Walton et al. 2003).

3.3.3 Financial reporting in the U.S.A

Similar to the UK financial reporting, but contrary to the French reporting, the USA financial reporting is based on common law. The accounting principles and practices of the USA are

influential beyond the country's national boundary and have, of themselves, provided a means of harmonization for those other countries and business enterprises choosing to follow the USA lead. They act also as a block to harmonization where the USA regulators will not accept any practices other than those conforming to USA standards without a statement of reconciliation of the differences. The source of the widespread influence of USA financial reporting lies in its worldwide political and economic dominance and in the importance of its capital market. The market is closely regulated by an agency of the federal government, the Securities and Exchange Commission (SEC). Those companies which seek a listing of their shares must comply with SEC regulations.

Within this framework of close regulation, there is considerable scope for application of professional judgment in financial reporting matters. Financial reporting standards are greater in volume and more detailed than those of almost any other country in the world, but they are set by an independent standard setting body rather than by statute law. The standard setting body has been well supported financially, and has therefore researched issues to an extent not feasible in other countries. The entirety of USA financial reporting principles and practices is referred to as "US GAAP", short for "US generally accepted accounting principles" (FASB, 1997, p.1). The concept of such a set of written principles originates in the USA, although the abbreviation is used in reference to other countries also. Accounting disclosure is characterized by openness and financial reporting measurement by general conservatism and historical cost. Such conservatism originated in the stock market crash of 1929, modified by business pragmatism and flexibility in response to events of more recent years (Weetman, 2005; Walton et al. 2003; Nobes and Parker, 2004).

Using the scores developed by Hofstede (1984), Gray's method of analysis may be used to predict that the financial reporting system in the USA will be characterized by strong

professionalism, strong flexibility, strong conservatism and strong transparency. The strong professionalism is embedded in the historical development of the accounting profession and the responsibility taken by the profession for setting financial reporting standards. Statutory control is a reserve power but is rarely implemented in practice. Flexibility is seen in the lack of prescribed formats of presentation and the separate existence of tax law and accounting law. Insistence on historical cost would place the USA in a highly conservative category, but other aspects of detail in practice give glimpses of practices which are not always directed towards conservatism. Transparency is seen in the very extensive disclosures required by law and practice, particularly in the basic information package required by the Securities and Exchange Commission (SEC) of all listed US firms (Land and Lang, 2005; Weetman et al., 2005, Walton et al. 2003).

3.4 Comparative analysis of the financial reporting systems in the UK, USA and France

Since the main purpose of this study is to provide evidence regarding the value relevance of operating earnings and cash flows in the US, UK and French capital markets, it is important to take into consideration the financial reporting differences between these countries and determine how they may affect the value relevance of earnings and cash flows. Tables 3-6 show the financial reporting requirements and the accounting standards and practices used in these countries.

Evidence shows that there are significant financial reporting differences between these countries despite the efforts to be minimised through the adoption of either the International Accounting Standards or even the European Union Directives. Financial reporting in the UK and the US has several similarities due to the fact that it is based on the Anglo-Saxon system. On the other hand, the UK and the French financial reporting systems have fewer similarities even though both countries follow the EU accounting directives. More specifically, in France firms give the same

reports for financial reporting and tax purposes. Consequently, France is more conservative in the preparation of financial statements and tax rules override accounting rules. This affects the accounting treatment of discretionary items and causes differences between this country and the others that give different reports. A difference that arises between countries that give the same reports for tax purposes and for financial reporting like France and those that are not is that deferred taxation generally does not arise for the first one. In the US and UK deferred taxation exists because the income calculated for tax purposes differs from the income for financial reporting. Another difference is the use of accelerated methods of depreciation in France, which leads to lower income. Main providers of capital in France are the government and banks. The accounting profession has limited power (see Table 4) (Bartov et al. 2001; Weetman, 2005; Walton et al. 2003).

Table 4

Summary of major differences and expectations between Anglo-Saxon
and code law countries

Major Differences	Anglo-Saxon Countries	Code Law Countries
Drivers of Influence	<ul style="list-style-type: none">• Capital Markets	<ul style="list-style-type: none">• State• Financial Institutions

Alignment of Financial and Tax Accounting	<ul style="list-style-type: none">• Low Level	<ul style="list-style-type: none">• High Level
Expectations	<ul style="list-style-type: none">• Higher R^2• High Quality of Earnings• CFFO Importance	<ul style="list-style-type: none">• Lower R^2• Low Quality of Earnings• CFFO Importance

There are several similarities between USA and UK financial reporting. However, USA is more conservative as indicated in the following analysis and this affects its accounting practices. SEC has the authority to set detailed rules for Financial Statements. Contrary to the USA financial reporting system, the UK accounting system focuses on the information needs of investors, it is more flexible and less conservative to measurement techniques. In the UK there is not such legal power as the SEC in the USA. There are certain laws and established practices that must be followed. Security markets have significant influence on accounting practice but do not dominate the process of accounting regulation. The accounting profession is influential in the accounting regulatory process (Nobes and Parker, 2004; Bartov et al. 2001; Weetman, 2005; Walton et al. 2003).

TABLE 5

Summary of financial reporting standards in the USA, the UK and France

Type of difference	USA	UK	FRANCE
Reports/Differences between Taxation and Accounting Rules	Different reports for tax purposes and financial reporting Taxation rules differ from the accounting rules Accounting Income higher than income for tax purposes	Different reports for tax purposes and financial reporting Taxation rules differ from the accounting rules	Same reports for tax purposes and financial reporting for legal entities. This does not apply for consolidated financial statements. Accounting rules are almost similar with tax rules
Effect on Earnings/ Sign of conservatism ⁴	0 / N	0 / N	- / Y
Goodwill	As per FASB 142, goodwill is no longer amortized. But during the period covered by empirical tests, the maximum period of amortization was 40 years	Write-off directly against reserves Capitalization is permitted	Is calculated on the basis of fair value or on the basis of book values. No period of time is required for amortization (PCG 2103). But during the period of empirical tests the usual period of amortization was 20 years
Effect on Earnings/ Sign of conservatism	+ / N	Depends on the method used	+ / N
R&D Expenditures ⁵	Expensed immediately (except software Development Costs). R&D is capitalized for the Oil industry.	Research must be written-off as incurred but development costs may often be capitalized	May be capitalized and amortized over a period of not more than 5 years. Generally expensed as incurred
Effect on Earnings/ Sign of conservatism	- / Y	- / N	- / Y
Depreciation	Straight-line method but accelerated methods are acceptable	Straight-line method Accelerated methods also permitted	Straight line and accelerated methods. Rates are determined by the tax authorities only in fiscal accelerated method.
Effect on Earnings/ Sign of conservatism	Depends on the method	Depends on the method	- / Y
Leases	Capitalized	Capitalized	Have to be capitalized in consolidated financial statements. But capitalization not allowed in the statement of the legal entity
Effect on Earnings/ Sign of conservatism	0	0	0
Major influences	Security Market	Company Law Security Market Accounting profession Stock Exchange European Union	Company Law Taxation European Union

⁴ + : positive effect ; - : negative effect; 0: no effect; Y: conservatism; N: no conservatism

⁵ + : positive effect ; - : negative effect; 0: no effect; Y: conservatism; N: no conservatism

Table 5 (continued)

Type of difference	USA	UK	FRANCE
Method of Consolidation	Equity method (20-50% ownership) Purchase method (51-100 % ownership). Pooling of interest method not allowed after 2001 (FASB 141)	Equity method (20-50% ownership) Purchase method and Pooling of interest (51-100 % ownership)	Purchase method, equity method, and proportional integration methods are allowed. The pooling of interest method has been allowed since 1999.
Inventory Valuation	Lower of cost and Market (Replacement Value) FIFO, LIFO, weighted average and specific identification are permitted. LIFO is the most frequently used method.	Lower of cost and Net Realizable Value LIFO is not permitted.	Lower of cost and market value. LIFO is not permitted for tax purposes. Allowed in financial statements (but not used in practice).
Effect on Earnings/ Sign of conservatism ⁶	- / Y	+ / N	+ / N
Valuation of fixed assets	Historical cost but write-downs to market value are permitted when necessary	Historical cost but replacement values are permitted (current cost)	Historical Cost
Effect on Earnings/ Sign of conservatism	- / Y	Depends on the method	- / Y
Long-term contracts	Both completed contract and percentage-of-completion methods are allowed. % of completion method is recommended.	Percentage-of-completion	Both completed contract and percentage-of-completion methods are allowed. % of completion method is recommended.
Effect on Earnings/ Sign of conservatism	0	0	- / Y
Deferred taxation	Liability method (comprehensive allocation)	Liability method (partial allocation)	Generally does not arise Deferral method or Liability
Foreign currency translation	At the closing rate	At the closing rate	Current rate and closing rate methods are allowed and used.
Major influences	Security Market	Company Law Security Market Accounting profession Stock Exchange European Union	Company Law Taxation European Union

⁶ + : positive effect; - : negative effect; 0: no effect; Y: conservatism; N: no conservatism

Specific financial reporting differences among the three countries follow (see also Table 5) (Weetman, 2005; Haskins et al., 2000; Walton et al. 2003; Nobes and Parker, 2004, Lee et al. 2005).

Financial reporting vs tax rules:

In UK and USA there exist different reports for tax purposes and financial reporting purposes. In contrast, in France there exist same reports for both financial reporting and tax purposes for legal entities (consolidated financial statements are out of the scope of tax regulations, so much more freedom is allowed. However, consolidated financial statements are the aggregation of the financial statements of legal entities, so because the legal entities have to refer to tax rules, the consolidated financial statement are highly influenced by tax regulation). This requirement in France makes parent firms be more conservative in their reporting. Thus, on average earnings for financial reporting purposes in France are expected to be underestimated, whereas in UK and USA earnings are expected to be overestimated.

Goodwill

In the USA and France today and under the International Financial Reporting Standards (IFRS) goodwill is capitalized but not amortized. During the period of the study this was not the case: amortization of goodwill was the usual procedure. In the UK goodwill is generally written off against reserves, although capitalization is permitted.

Treatment of Research and Development (R&D)

Research and Development expenses are capitalized and amortized in France over a five year period. In the USA R&D is expensed immediately with the only exception the software development costs and research in the oil industry. In France although capitalization is permitted generally this cost is expensed as incurred. This makes USA and France more conservative. This financial reporting policy leads to lower earnings in France and in USA. As far as UK is

concerned, research cost must be written off as incurred but development costs may often be capitalized.

Depreciation

The depreciation method most frequently used in all countries is the straight-line method. However, in the USA, UK and France accelerated methods are also permitted. In France the straight line method is the most frequently used method. Accelerated methods of depreciation are also used because of the conservatism that exists in the country due to the fact that companies give the same reports for tax and financial reporting purposes. This leads to lower level of earnings for these firms.

Leases

Leases can be classified as operating or capital. Operating leases must be expensed, whereas capital leases are capitalized. In USA and UK leases can be classified as either operating or capital, whereas in France leases have to be capitalized in consolidated financial statements (capitalization not allowed in the financial statements of the legal entity).

Method of consolidation

In the USA and UK the same methods apply for ownership in third companies. More specifically, the cost method applies for ownership up to 20%, the equity method applies for ownership between 20% and 50%, whereas the purchase method applies for ownership more than 50%. As far as France is concerned the purchase method, the equity method and the proportional integration methods are allowed. The pooling of interest method has been allowed since 1999.

Inventory Valuation

The LIFO method for inventory valuation is also permitted in the USA, which results in lower profits during inflationary periods. In contrast, in the UK and France LIFO is not permitted for tax purposes. Furthermore, in the USA the lower of cost and replacement value are used whereas in the

UK the lower of cost and net realizable value methods are used. Thus, this inventory valuation standard leads to more conservatism in the US and to less conservatism in France and in the UK.

Asset Valuation

Revaluation of fixed assets is permitted in the UK. In the USA write-downs to market value are allowed when necessary. In France historical cost is used and even if re-evaluation is allowed it is never used (except when there is no tax effect which was the case in 1976 and 1978). Thus, the USA and French financial reporting systems are more conservative with regards to the valuation of fixed assets.

Deferred Taxation

Deferred taxes arise when taxation rules differ from accounting rules. Consequently, this occurs in countries that allow different reports for tax and financial reporting purposes. Thus, USA and UK, which allow different reports, deferred taxation exists and it is treated under the liability method. On the contrary, in France companies give the same reports for tax and financial reporting purposes and deferred taxation generally does not arise.

Statement of Cash Flows

In Anglo-Saxon countries (UK and USA) the preparation of the Cash Flow Statement along with the other financial statements (Income Statement and Balance Sheet) is required. In France, the cash flow statement has been mandatory since 1999 (regulation 99-02-426). Prior to 1999, the cash flow statement was highly recommended (OECCA, rec n° 1-22 and OEC 30-1997). In other Code Law countries the preparation of cash flow statements is not required with the exception of Japan, where it is required only for the parent company. As it can be seen, the absence of the need to provide investors with public information in most Code Law countries have not stressed the need of preparation of Cash Flow Statement.

Finally, from the above analysis we can derive some conclusions regarding the

conservatism of each country and the effect of these accounting practices on the importance of earnings for investors. The financial reporting in the USA and France seems to be more conservative than the financial reporting in the UK. The conservatism of France is reinforced by the link between financial reporting and tax law. Specifically, in France historical cost is used for the valuation of the fixed assets. USA and France expense R&D costs as incurred. French firms, in addition to the straight line method, also use accelerated methods of depreciation and these methods are also acceptable in the USA. LIFO method for the valuation of inventory is acceptable in the USA.

Furthermore, these financial reporting practices affect earnings and their usefulness to investors (Chan et al., 1991; Heston et al., 1995; Pae et al. 2005; Nobes and Parker, 2004). Conservative accounting methods and measurements result in lower earnings. USA and France are expected to have lower earnings compared to UK. Moreover, investors would characterize French earnings less reliable because of their conservative system. Hence, we expect cash flows to be more value relevant in France. Table 3 presents the major requirements regarding the financial reporting requirements that firms must follow as well as the accounting principles that they have to obey in order to prepare their financial statements. As it can be seen, UK and USA have more financial reporting requirements than France. This is partly due to the fact that the major influences in financial reporting in both USA and UK come from the capital markets whereas in France financial reporting is based mainly on law derived from taxation and code law.

Table 6 presents further reporting requirements that relate to the sources of generally accounting principles (GAAP), interim financial reporting, and annual reporting requirements. In the USA, the GAAP are based on the Financial Accounting Standards Board (FASB). In the UK, the source of GAAP is the 1985 Companies Act and the Accounting Standards Board. In France the source of GAAP is the Commercial Code, Plan Comptable General. As far as the

governmental agency that regulates the public firms is concerned, USA firms are subject to the Securities and Exchange Commission (SEC), UK firms are subject to the Registrar of Companies, whereas French firms are subject to the Commission des Operations de Bourse (Weetman, 2005; Haskins et al., 2000; Walton et al. 2003; Nobes and Parker, 2004, Lee et al. 2005).

Table 6: Financial Reporting Requirements in the USA, the UK and France

Type of difference	USA	UK	FRANCE
Source of GAAP	Financial Accounting Standard Board Securities and Exchange Commission	Company Act 1985, amended Companies Act 1989 Accounting Standards Board ISEs Continuing Obligations	Commercial Code Plan Comptable General
Interim reporting requirements	Quarterly	Semi-annual	Semi-annual Quarterly revenues

Annual reporting requirements from FYE	90 days of FYE	6 months of FYE	45 days after annual meeting which must be held within 6 months of FYE but a preliminary report published within 4 months of FYE and 15 days before annual meeting
Governmental Agency Regulating Public Companies	Securities and Exchange Commission	Registrar of Companies	Commission des Operations de Bourse
Alignment of Financial and Tax Accounting	Low level	Low level	High level
GAAP required for Financial Accounting	US GAAP	UK GAAP	French GAAP IAS GAAP

Source: Haskins et al (2000); Nobes and Parker (2004); Alford et al. (1993); Gonzalo and Gallizo (1992).

As far as annual reporting requirements from fiscal year end is concerned, USA firms must file their annual reports 90 days after the fiscal year end, whereas UK firms must file annual reports up to six months after the fiscal year end. As far as French firms is concerned, they have to file their annual reports 45 days after annual meeting which must be held within 6 months after the fiscal year end but a preliminary report should be published within four months after the fiscal year end and 15 days before the annual meeting. Thus, US firms file their financial reports much earlier than UK and French firms (Lee et al. 2005; Walton et al. 2003; Nobes and Parker, 2004).

3.5 Differences in the value relevance of earnings between Anglo-Saxon countries (USA and UK) and France.

In the previous sections of the study, the major financial reporting differences between Anglo-Saxon countries and France were critically evaluated. These differences in financial reporting are expected to have an effect on the earnings figures reported by each firm. One of the major research questions raised in prior studies and in the present study is whether these earnings differences play an important role in the valuation of securities. One would expect the association of earnings with security returns to be higher in Anglo-Saxon countries (USA and UK) than in France for the following reasons. First, in Anglo-Saxon countries, where financial reporting is basically influenced by common law, accounting practices traditionally rely on professional judgment. This permits discretion in the preparation of financial statements as long as they provide a 'true and fair view' of firm's position. In contrast, in France, because of the influence of the code law system, accounting rules are provided by a national accounting plan defined by governmental committees. This implies a high level of standardized practices that can be in opposition with the true and fair view approach. To the extent that the adoption of this approach is expected to provide more value relevant

financial reporting figures, the association between earnings and security returns is expected to be higher in Anglo-Saxon or code law countries (USA and UK) than in code law countries (i.e. France).

Secondly, the tax system has a strong influence on financial reporting rules and practices in France since the figures in the financial reports form the basis for those in the tax accounts. In contrast, the alignment of financial reporting with tax reporting is relatively low in Anglo-Saxon countries (USA and UK). This difference might tend to lead firms to systematically adopt tax minimizing reporting techniques so that earnings may not reflect economic reality, which is supposed to weaken the association of earnings with security returns (Haskins et al. 2000; Weetman, 2005).

Thirdly, because firm financing is mainly provided by widely dispersed small shareholders in the USA or in the UK, the financial reporting systems strongly focus on earnings measures. In France, ownership being largely in the hands of banks or family members that have direct access to internal financial information and firms relying heavily on debt financing, the accounting principles mostly focus on reporting to creditors. Thus, this may reduce the relevance of accounting numbers for shareholders and their association with security returns (Dumontier, 1998; Frylender and Pham, 1996; Nobes and Parker, 2004).

3.6 Financial reporting in the UK: Financial Reporting Standard No. 1 (FRS # 1) and the Statement of Cash flows

The FRS No 1. “Cash Flow Statement” was introduced in 1991 to replace the SSAP No 10 entitled ‘Statement of Source and Application of Funds’. This statement establishes standards for cash flow reporting. It has been effective in respect of financial statement relating to accounting periods ending on or after 23 March 1992. This cash flow statement was issued by the

UK Accounting Standard Board due to the changing economic environment which had led to increasing sophistication in the requirements of users of financial information. Moreover, there has been a widespread belief that the profit presented in the traditional financial statements does not always give a comprehensive picture of the company's operations, firm's liquidity, solvency, and financial flexibility (Nobes and Parker, 2004).

According to the FRS #1, the cash flow information i) may assist users of financial statements in making judgements on the amount, timing and degree of certainty of future cash flows; ii) gives an indication of the relationship between profitability and cash generating ability. Cash flow information, together with balance sheet data, provides information on the firm's liquidity, viability and financial adaptability. Balance sheet data provide information about an entity's financial position at a particular point in time, including assets, liabilities and shareholder's equity. However, it does not provide complete information on liquidity, since it is drawn up at a particular point in time. On the other hand, a cash flow statement shows information about the reporting entity's cash flows in the reporting period, but this information is incomplete for assessing future cash flows, since only part of the current cash flows is expected to result in future cash flows. Therefore, cash flows should be used in conjunction with profitability and Walton et al. 2003).

Prior to the issuance of this cash flow statement standard, emphasis was given to the working capital concept. The following are some of the advantages of cash flow statements over funds flow (working capital based) statements:

- i) Funds flow data can hide movements relevant to the liquidity and viability of an entity. For example, a significant decrease in cash availability be masked by an increase in stock or debtors. Entities may, therefore, run out of cash while reporting increases in working capital.

- ii) Cash flow monitoring is not a specialized accounting technique and is therefore a more widely understood concept than are the changes in working capital.
- iii) Cash flow can be a direct input into a business valuation model, therefore historical cash flow may be relevant in a way not possible for funds flow data.
- iv) The funds flow statements is based largely on the difference between two balance sheets and it does not provide new data. The cash flow statement and the notes to it, may include additional data.
- v) Cash flow is more comprehensive than profit which is dependent on accounting convention and concepts.
- vi) Creditors are more interested in an entity's ability to repay them than in its profitability. Whereas “profits” might indicate that cash is likely to be available, cash flow accounting is more direct with its message.
- vii) Cash flow reporting provides a better means of comparing the results of different companies than traditional profit reporting.
- viii) Cash flow reporting satisfies the needs of all users better:
 - a) Creditors mentioned above
 - b) for management, it provides the sort of information on which decisions should be taken (in management accounting), relevant costs to a decision are future cash flows
 - c) for shareholders and auditors, it provides a satisfactory basis for stewardship accounting.
- ix) Cash flow reporting should be both retrospective, and also include a forecast for the future. This is of great information value to all users.

Even though cash flow information has certain advantages, it is not without its

limitations. A cash flow statement is a record of historical facts. It will record expenditure upon additional plant and machinery, for example, but it can express no opinion on whether the expenditure was necessary or will be profitable. Similarly, it may show an expansion of inventory, but it will not show whether this was due to poor inventory control, or to the organization's inability to sell the finished product. Moreover, the cash flows will show how new capital was raised, but not whether it was raised in the best way nor whether it was really needed to be raised at all. In addition, a cash flow statement may highlight a deteriorating situation, but it does not show how close a company is to the limit of its facilities or whether the company has liquidity or solvency problems. Finally, the cash flow statement shows only the cash flows for the year which ended very recently (some months ago), but unfortunately liquidity problems can arise very quickly. Therefore, even though the newly established cash flow statement has several advantages, it should be used in conjunction with the other financial statements (such as balance sheet and profit and loss). Indeed, the cash flow information can signal liquidity and solvency problems that could be very useful to creditors, investors and management so they can take action to prevent future organizational and financial problems (Uhrig-Homgurg, 2005).

3.7 Comparative analysis of the empirical evidence on the value relevance of earnings and cash flows in the UK, the USA and France

In this section I provide a critical review and a comparative analysis of the empirical studies that have been undertaken regarding the value relevance of earnings and cash flows in the three countries under examination, namely, UK, USA and France. As it can be seen in the discussion that follows the majority of the studies undertaken thus far relate to the USA empirical evidence.

Furthermore, the value relevance of cash flows has been examined more extensively only in the past decade. Earlier studies examined mainly the value relevance of earnings.

The discussion that follows is broken down originally by country and thereafter I discuss in more depth the studies that examined more than one country. Specifically the following issues will be discussed: i) Empirical Evidence on the value relevance of earnings and cash flows in the USA, ii) Empirical Evidence on the value relevance of earnings and cash flows in the UK, iii) Empirical Evidence on the value relevance of earnings and cash flows in France, iv) Comparative analysis of the empirical evidence on the value relevance of earnings and cash flows in the UK, USA and France. A discussion of the above issues follows.

3.7.1 Empirical evidence on the value relevance of earnings and cash flows in the USA

Since the seminal study of Ball and Brown (1968), several studies have indicated that earnings possess information content, which appears to be robust across time periods, statistical methodologies and stock exchanges in which shares are traded (Barth et al. 2005; Land and Lang, 2005; Kothari, 2001; Barth, Beaver and Landsman, 2001; Lev and Ohlson, 1982). Even though empirical studies have shown that earnings is the dominant measure for explaining security returns, researchers have maintained that the accrual process is subject to significant manipulation. Moreover, the model's explanatory power as explained by the adjusted R^2 is relatively low. Therefore, researchers have examined not only the value relevance of earnings, but also the value relevance of cash flows beyond earnings.

Among the first researchers who examined the value relevance of earnings and cash flows in the USA capital markets were Wilson (1986, 1987), Rayburn (1986), Bernard and Stober (1989) and Livnat and Zarowin (1990). The results of all those studies were robust with regards to the value relevance of earnings and mixed and inconclusive regarding the value relevance of cash flows

beyond earnings. The results of the studies by Rayburn (1986), Wilson (1986,1987), Bowen et al. (1987) showed that cash flows provided some explanatory power beyond earnings in explaining security returns. Studies by Bernard and Stober (1989) and Livnat and Zarowin (1990) who extended prior cash flow studies showed that the separation of earnings into cash flows and accruals does not improve significantly the value relevance beyond that explained by earnings alone.

Since early studies on the value relevance of earnings and cash flows did not provide conclusive results regarding the value relevance of cash flows in explaining security returns beyond earnings, possibly due to the fact that these studies are based upon the pooled data of many firms, under the assumption that the returns-earnings/cash flows relation is homogeneous across firms. Empirical studies in the past decade have progressed into a new arena, which relaxes the assumption of the homogeneity of returns earnings/cash flows relation, and assumes that the value relevance of earnings and cash flows is based on certain contextual factors, such as a) the return window or interval of earnings and cash flow measurement, b) the transitoriness or permanence of earnings and cash flows, c) other contextual factors such as the level of the operating cycle and the industry that the firm belongs to. A discussion of the studies that relate to those contextual factor follows.

3.7.1.1 Empirical evidence on the value relevance of earnings and cash flows when long return intervals or windows are considered.

Since one of the major problems of most earnings-returns studies was the low explanatory power of the models, Easton, Harris and Ohlson (1992) extended this type of research by taking into consideration longer windows for the return and earnings variables. By doing that, one of the major problems associated with earnings that has to do with accruals management is mitigated to a great

extent as the measurement interval increases. Easton, Harris and Ohlson (1992) and Warfield and Wild (1992) used USA data to examine the association of earnings with security returns. The results of these studies provided evidence that the association of earnings with security returns improves over longer measurement intervals. Easton et. al., showed that for a five-year return interval the R^2 is equal to 33%. For the annual return interval the R^2 is only 5%. These researchers examined only the value relevance of earnings over longer return intervals.

In contrast, Dechow (1994) examined also the value relevance of cash flows over longer return intervals. Dechow hypothesized that over longer measurement intervals, cash flows will suffer from fewer timing and matching problems, the importance of accruals will diminish, and therefore, earnings and cash flows are expected to converge as measures of firm performance. Cash flows suffer more from timing and matching problems over short measurement intervals because they have no accrual adjustments and the accruals associated with cash flows are long term in nature and they do not reverse in the short-run (Dechow, 1994).

On the other hand, the explanatory power of earnings compared to cash flows is expected to be the highest over short measurement intervals, because earnings include current and noncurrent accruals that mitigate the timing and matching problems related to the organization's operating, investing and financing cash flows. Moreover, Generally accepted accounting principles trade off relevance and reliability so that accruals do not completely mitigate all short term timing and matching problems in realized cash flows. Dechow (1994) used US data. Results show that there is a relative increase in the explanatory power of cash flows compared to earnings over longer measurement intervals. More specifically, Dechow examined the value relevance of earnings and cash flows over a quarterly, annual and a four year period. The explanatory power of the earnings models as measured by the adjusted R^2 was as follows: 3.24% over the quarterly period, 16.20% over the annual period and 40.26% over the four year return interval. As far as

the cash flow models is concerned, the explanatory power of these models as measured by the adjusted R^2 was as follows: 0.01% over the quarterly period, 3.18% over the annual period and 10.88% over the four year return interval. The following conclusions can be drawn from this study: a) that the explanatory power of earnings is greater in all three intervals tested, b) the explanatory power of both earnings and cash flows increases as the measurement interval increases, and c) the explanatory power of the cash flow models compared to the explanatory power of the earnings model increases at a higher rate as the measurement interval increases. It was less than 1% (R^2 of earnings model divided by the R^2 of the cash flow model) in the quarterly interval and it reached 27% in the four year interval.

In summary, these studies provide evidence that as the measurement interval increases, the value relevance of both earnings and cash flows improves. However, none of those studies used multivariate analysis to examine the value relevance of both earnings and cash flows. These studies used univariate analysis (Chambers, 2004).

3.7.1.2 Empirical evidence on the value relevance of earnings and cash flows when transitoriness or permanence of earnings is considered.

In the previous part I discussed the contextual factor that relates to the value relevance of earnings and cash flows when the measurement interval increases to more than one year. In this part I discuss the empirical evidence that relates to the value relevance of earnings and cash flows when earnings are transitory. Both contextual factors have a common objective. To identify specific circumstances where the value relevance of earnings and cash flows is altered (improves or deteriorates). Using USA data, Freeman and Tse (1992) and Ali (1994) showed that transitory earnings have smaller marginal impact on security returns. Cheng et al (1996) extended these studies by hypothesizing that when earnings are transitory, the value relevance of earnings

diminishes, whereas the value relevance of cash flows is expected to increase. Earnings transitoriness was measured as the earnings change scaled by the beginning of period price and also by the earnings to price ratio. Extreme values of these measures could be considered as an indication of earnings transitoriness. Transitory items are expected to have limited valuation implications. Examples of transitory items in earnings include current and long-term accruals such as losses due to restructuring, current recognition through asset sales of previous periods' increases in market values, one time impact on income from changes in accounting standards. The results of the Cheng et al. (1996) study indicated that a) when level and changes in earnings and cash flows are included in the model, all are value relevant in the marketplace, and b) when earnings are transitory the value relevance of earnings diminishes substantially, and simultaneously the value relevance of cash flows increases.

In summary, these results are indeed of great importance since earlier studies assumed that the earnings returns relation is homogeneous across firms. These studies, however, disprove this assumption and indeed show that the value relevance of earnings and cash flows depends on the permanence or transitoriness of these measures.

3.7.1.3 Empirical evidence that examined other contextual factors such as the level of the operating cycle and the industry that the firm belongs to.

In addition to the aforementioned contextual factors that relate to the long-windows effect and to the earnings permanence, researchers tested additional factors in order to determine the value relevance of earnings and cash flows. Additional contextual factors examined were a) the level of the operating cycle; b) the size of accruals; and c) industry factors.

Specifically, Dechow (1994) examined whether the level of accruals and the size of the operating cycle play an important role in explaining security returns. The results indicated that both the

operating cycle and the size of accruals are important determinants in explaining security returns. Specifically, Dechow hypothesized that earnings (cash flows) are expected to outperform cash flows (earnings) in the marketplace when a) accruals are large (small), and b) when firms are not in a steady state (steady state) [eg., firms that belong in the construction industry and thus have long term contracts and volatile annual cash flows]. Dechow showed that cash flows are associated more with security returns when cash flows and earnings are most similar., ie., when the magnitude of the absolute accruals is relatively small.

As far as the operating cycle is concerned, Dechow showed that in industries where the operating cycle is long, working capital requirements are more volatile and earnings better reflect firm's performance than cash flows. Additional studies that examined the value relevance of earnings in different industries include Biddle and Seaw (1995). Their results indicated that the value relevance of earnings is industry specific.

In summary, USA results provided evidence that earnings permanence, the level of the return window and industry classification play an important role in explaining security returns. However, more research remains to be conducted to provide more robust results on the value relevance of cash flows beyond earnings.

3.7.2 Empirical evidence on the value relevance of earnings and cash flows in the UK

The association between earnings and cash flows with contemporaneous security returns has also been analyzed with UK data. In general , results show that, in UK, like in the USA this association is not that robust, as this association is measured by the adjusted R^2 . These results suggest that reported earnings and cash flows do not provide a strong summary measure of the value-relevant events that have been incorporated in security returns during the reporting period. Specifically, one of the early UK studies by Board and Day (1989) failed to find incremental information content

for operating cash flow beyond accounting earnings. Moreover, Strong (1993) examined the association of earnings with security returns for UK firms. His results showed that the average adjusted R^2 of the models tested was about 10%. This relatively low association observed between earnings and security returns suggests that earnings capture only a weak proportion of the information incorporated in security prices. It is often argued that information included in stock prices is richer than the one reflected by earnings alone because investors focus on all events that affect expected future cash flows, while earnings incorporate only those that have met the conditions for accounting recognition. Since relevant events that are not captured in contemporaneous earnings would normally be captured in subsequent periods, there should be a lag in the inclusion of new information into earnings, and stock prices should be more prompt than earnings in reflecting new information. This recognition lag causes both an errors-in-variable problem and an omitted variable problem because earnings do not reflect some information captured in current returns, whereas they reflect some information that was captured in prior returns (Dumontier and Raffournier, 2002; Nobes and Parker, 2004; Walton et al. 2003).

Moreover, Alford et al. (1993) showed that UK earnings are valued in the marketplace. UK earnings were shown to be more value relevant and timely than US earnings. Furthermore, Ali and Pope (1995) provide evidence that the absolute size of unexpected operating cash flows conditions the security response to this accounting variable and that, while operating cash flow cannot be shown to have incremental information content beyond accounting earnings in simple cross-sectional regressions, evidence in support of incremental information content is only provided when the cash flow response coefficient is allowed to decline as the absolute size of unexpected cash flow increases.

McLeay et al. (1996) used firm-specific forecast models to estimate innovations in accounting variables, focusing on the relative information content of earnings and operating cash

flows using both time series and pooled cross-sectional approaches. McLeay et al. (1972), using a similar dataset to Ali and Pope (1995), find support for incremental information content of operating cash flow, obtaining a similar R^2 for the incremental information model to results reported by Ali and Pope. While the use of firm-specific forecast models to estimate earnings and cash flow innovations may have advantages over an approach that uses a standard measurement approach for all firm-year accounting variable observations (such as first difference or first difference and level of variable), measurement error in the estimation of the forecast model is likely to affect the findings. The relatively low earnings response coefficients reported by McLeay et al. (1992) (less than 1.0 compared with approximately 2.0 in Ali and Pope, 1997) suggests that measurement error may have affected the reported regression coefficients.

Furthermore, Clubb (1995) showed that cash flows from operations, accruals and earnings are all positively related to stock returns, but accruals adjustments seem to possess information content beyond that reflected by cash flows and earnings. In addition, Green (1999) showed that the value relevance of UK cash flows was unsurprisingly related to the correlation between accounting earnings and operating cash flows, results consistent with those provided by Charitou (1997).

In summary, empirical evidence in the UK shows that earnings are valued in the marketplace beyond cash flows but the explanatory power of earnings, as measured by the R^2 is not that robust. As far as the value relevance of cash flows is concerned, results have been mixed and inconclusive.

3.7.3 Empirical evidence on the value relevance of earnings and cash flows in France

As far as the empirical evidence on the value relevance of earnings and cash flows in explaining security returns, French evidence has been limited. In general, results on the value relevance of

earnings show that earnings play an important role in explaining security returns. Researchers who examined the value relevance of earnings in France, include among others, Dumontier and Labelle (1998), Ball, Kothari and Robin (2000), Alford et al, 1993, Joos and Lang (1994), Ali and Hwang (2000).

Alford et al (1993) examined the value relevance of earnings in France. They showed that earnings in France are value relevant and even more relevant and timely than US earnings.

Joos and Lang (1994) provided similar reconfirm the results of Alford et al. They showed that earnings in France are value relevant and are valued more than common law countries, such as UK. In contrast, Ali and Hwang (2000) provided opposite results. They regressed stock returns with scaled earnings to explore the impact of French earnings on security returns. Their results showed that even though earnings are value relevant, French earnings were less value relevant than US earnings.

Furthermore, Dumontier and Labelle (1998) examined the association of earnings with security returns. Their results indicated that earnings are valued in the marketplace. The variability of their results were however very high and yearly dependent. Their R^2 's ranged from 1% to 49%. Dumontier and Labelle (1998) extended their study to examine the effect on earnings on security returns over long return windows. Their results indicated that the correlation between earnings and returns improves with increases in the time interval under consideration. They obtained R^2 's ranging from 15% for the one year interval and to 39% for the five year interval.

In addition, a study by Ball et al (2000) showed that earnings in France are value relevant but earnings are less timely and less conservative compared to USA earnings. They hypothesized, though, that income reported in France is more smoothed and less timely in incorporating current period changes in market value compared to a common law country, such as USA.

In addition to the aforementioned studies, researchers also examined the market response to

French earnings. Results in general support the hypothesis that positive unexpected earnings lead to positive abnormal returns (Gajewski and Quere, 2001).

In summary, even though research on the value relevance of earnings in France has been limited, existing empirical evidence indicates that earnings are valued in the marketplace. As far as the value relevance of cash flows in France is concerned, researchers have not examined the value relevance of cash flows beyond earnings.

In concluding, due to the very limited research on French earnings and cash flows, much more research is needed in France on the value relevance of earnings and cash flows.

3.7.4 Comparative analysis of the empirical evidence on the value relevance of earnings and cash flows in the UK, the USA and France.

In this section, I will discuss those empirical studies that compared and contrasted the value relevance of earnings or cash flows or both in a comparative way in at least two of the three countries utilized for this study. More specifically, the following comparative studies were undertaken that will be discussed in this section: Alford et al (1993), Joos and Lang (1994), Pope and Walker (1999), Ali and Hwang (2000), Ball, Kothari and Robin (2000) and Bartov, Goldberg and Kim (2001).

A discussion and critical evaluation of the results of these studies follows.

Alford et al (1993) were among the first researchers who examined the value relevance of earnings in different countries. They observed considerable variation in the explanatory power of earnings in explaining security returns in the countries under investigation. Regarding USA, UK and France, results indicated that earnings from France and UK are more value relevant and timely than USA earnings.

Joos and Lang (1994) tried to verify some of the results provided by Alford et al. They

focused on financial reporting practices in France, Germany and UK. They found evidence of significant differences in the value relevance of earnings. Results indicated that UK earnings were less value relevant than in UK and Germany. The R^2 s of the models tested were greater in France and smaller in the UK.

Pope and Walker (1999) provided further evidence beyond the results provided by Alford et al. (1993). They examined differences in the timeliness and conservatism of income recognition between the USA and UK GAAP financial reporting regimes. Building on the Basu (1997) study, they focused on the links between current reported earnings and current and past stock prices. Their results indicated that the degree of conservatism displayed by earnings before extraordinary items under USA GAAP was higher than under UK GAAP. Results were opposite for earnings after extraordinary items. Thus, UK GAAP earnings are significantly more timely in the recognition of bad news than USA GAAP earnings. UK firms recognize bad news faster than USA firms, but they classify the bad news differently.

Furthermore, Ali and Hwang (2000) regressed market returns with scaled earnings to explore the impact of several country specific factors on the value relevance of financial information. Their results show that the degree of association between security returns and earnings is lower in code law countries as opposed to common law countries. More precisely, earnings in code law countries like France seemed more conservative and consequently less timely than those in common law countries, such as USA and UK.

Ball et al (2000) extended prior studies and examined the international differences in the demand for earnings predictably affect the way it incorporates economic earnings over time. They show that differences in the demand for earnings in different institutional contexts cause its properties to vary internationally. The properties examined were similar to those examined by Pope and Walker (1999), Ali and Hwang (2000), namely, timeliness and conservatism. They examined

more than 40000 firm year observations over the period 1985-1995 for 7 countries, among those USA, UK and France. Their results indicated that earnings in code law countries, such as France, is less timely and less conservative than common law income as reported in UK and USA. Comparing the UK and USA evidence, results indicate that there is less asymmetric conservatism in the UK earnings.

Finally, Bartov et al. (2001) investigated the value relevance of earnings and cash flows in five countries, two code law (not including France) and three common law countries, among those USA and UK for the period 1988-96. Their results indicated that earnings in Anglo-Saxon common law countries have more explanatory power than cash flows. Conversely, in the two code law countries (Japan and Germany), earnings are not superior to cash flows in explaining security returns. As expected, in all countries earnings had incremental information content beyond cash flows. In summary, results show that the superiority of earnings is not universal, but it depends on the financial reporting system under investigation, namely, code law versus common law.

In summary, results of comparative international studies indicate clearly that earnings are valued in the marketplace, but it is not clear if earnings in code or common law countries are valued more. As far as the value relevance of cash flows is concerned in different countries, evidence has been very limited. The major objective of my dissertation is to extend prior studies by examining in more depth the value relevance of both earnings and cash flows in code law and common law countries. Furthermore, in order to get more robust results I will use several methodologies, among those level and changes of earnings and cash flows, earnings permanence, long-return intervals and industry effects. It should be stressed that in all the aforementioned studies only one of the methodologies just alluded to is used and even some of them examined only earnings and not cash flows.

3.8 Summary of the critical literature review

In this chapter, the literature that relates to the value relevance of financial information (earnings and cash flows) was critically evaluated. Specifically, in this chapter an in depth discussion of two major issues was provided: a) the role of financial information in capital markets and b) comparative international financial reporting. As far as the first issue is concerned, an in depth critical evaluation was provided that related to i) the value relevance of earnings and cash flows, ii) the role of earnings in the capital markets, iii) the empirical evidence on the usefulness of earnings and cash flows in the marketplace, and iv) the use of contextual factors in improving the association between financial information and security returns. As far as the comparative international financial reporting is concerned the emphasis on the critical literature review was placed on i) the international classification of financial reporting, ii) the financial reporting in the three countries that will be examined empirically in the present study, i.e., France, UK, USA; iii) the comparative analysis of the financial reporting systems of those three countries, and iv) the critical evaluation of the major differences of the value relevance of earnings and cash flows between Anglo-Saxon countries and France.

Based on the critical discussion and analysis presented in this chapter, it is concluded that the value relevance of earnings and cash flows is still an open research question. Are earnings or cash flows valued more in Anglo-Saxon or code law countries? Are earnings or cash flows valued more in the service or manufacturing or retail industries? When the measurement interval increases, in which system, Anglo-Saxon or code law system, is there a greater increase in the value relevance of earnings and cash flows? When earnings are transitory, in which system, Anglo-Saxon or code law system, is there a greater increase in the value relevance cash flows?

These are some unanswered research questions in the capital markets literature. In this

dissertation I attempt to provide answers to the aforementioned questions. Specifically, this research study differs from prior studies in the following respects. First, it examines not only the value relevance of operating cash flows beyond earnings, but it also examines the role of cash flows in the capital markets after considering the industrial effects in both Anglo-Saxon and code law countries on the relative usefulness of operating earnings and cash flows in explaining security returns. Second, it examines the value relevance of earnings and cash flows when the measurement interval increases. Third, the above major research questions are examined empirically using data from UK and USA (Anglo-Saxon countries) and France (a code law country) in order to determine whether the valuation role of financial information differs in these countries. Fourth, this study examines comparatively the valuation of financial information such as earnings and cash flows, over longer measurement intervals for the UK, USA and France. Thus far, no other study has examined the above issues using comparative statistics for the U.K, US and France. Since there are several financial reporting, economic and social differences between the above countries, it is expected that this study will provide new insight regarding the effect, if any of these differences, on the value relevance of earnings and cash flows in these countries.

The critical literature review of this section will provide a groundwork for the chapters that follow, which relate to the theoretical framework, the motivation for the study/development of hypotheses, the methodology/research design and for the empirical analysis.

CHAPTER IV:

THEORETICAL FRAMEWORK AND DEVELOPMENT OF THE RESEARCH HYPOTHESES

This chapter discusses a) the theoretical framework, and b) the development of the research hypotheses.

4.1 Theoretical framework on the value relevance of earnings and cash flows

The theoretical relation between market prices and earnings draws on the classical dividend capitalization model. The market price (P) of an equity security at time t equals the present value of the expected dividend stream of discounted at risk-adjusted discount rate plus the expected liquidating dividend upon dissolution of the firm (Miller and Modigliani, 1961).

$$P_t = \sum (\text{Expected dividend} / 1+r)^t) \quad [1]^7$$

A liquidating dividend occurs because a firm generates cash flows each period that it does not fully distribute to shareholders as dividends. As long as a firm generates a return on the retained cash flows equal to the discount rate, or cost of equity capital, the firm's dividend policy has no effect on the market price of the common stock . This is the Miller and Modigliani (1961) dividend irrelevance proposition.

The source of cash flows for dividends is the cash flows generated by the firm . Cash flows received by the firm represent the generation of economic value; dividends merely represent the periodic distribution of this economic value to shareholders. Therefore,

7 Notation for all variables included in all the equations in this chapter is presented in alphabetical order at the end of this chapter.

$$P_t = \sum (\text{Expected cash flows} / 1+r)^t) \quad [2]$$

When a firm's expected leveraged free cash flows are projected to remain constant into perpetuity, a no growth scenario exists as follow:

$$P_t = \sum (\text{Expected cash flows} / r) \quad [3]$$

When leveraged free cash flows are projected to grow at a constant rate, g , then equation [3] becomes

$$P_t = \sum (\text{Expected cash flows}_{t+1} * (1/(r-g))) \quad [4]$$

The next step in the theoretical formulation of the price to earnings relationship substitutes a firm's expected earnings for its expected leveraged free cash flows in the preceding formulation of market price. This substitution of earnings for cash flows rests on the following:

- a. over sufficiently long time periods, net income equals leveraged free cash flows. The effect of year-end accruals to convert cash flows to earnings lessens as the measurement interval increases (Easton et al., 1991)
- b. For a no growth firm, net income equals leveraged free cash flow. For a firm experiencing a constant rate of growth, earnings is a constant multiple of leveraged free cash flows.
- c. Accrual based earnings reflect changes in economic values more accurately than do free cash flows.

By substituting expected earnings for expected cash flows in the cash flows market based equation, then the market price (P) equals

$$P_t = \sum (\text{Expected earnings} / 1+r)^t) \quad [5]$$

The final link in the chain relating market prices (P) to earnings substitutes actual earnings of the

most recent period for expected permanent earnings (no growth state)

$$P_t = \text{Actual earnings} / r \quad [6]$$

Possible justifications for using actual earnings in period t as surrogate for expected earnings in period $t+1$ are:

- a. actual earnings represent the permanent earnings level for the firm, and
- b. earnings follow a random walk, so the actual earnings of the current period are the best predictor of future earnings (Stickney, 1996).

Furthermore, Ohlson (1989) demonstrates that the Miller and Modigliani (1961) dividend irrelevance proposition becomes

$$P_t + \text{DIV}_t = \rho E_t + e \quad [7]$$

When a dividend is paid on security j at time t , where:

P = security price

DIV = dividend

E_t = expected (permanent) earnings

ρ = coefficient

e = error term

Furthermore, Feltham and Ohlson (1995), point out that measurements of operating accounting earnings focus on cash flows adjusted for accruals, and the use of accounting conventions for accruals generally leads to differences between the firm's market value and book value.

In an attempt to acquire an insight into the theoretical grounding of the relation between financial information and security prices, the determinants that lead to changes in the firm's market value and book value should be analyzed.

The theoretical framework developed in this study draws also from the clean surplus

relation (CSR), which implies that all changes in book value are reported as either income or dividends:

$$BV_t = BV_{t-1} + E_t - DIV_t \quad [CSR] \quad [8]$$

Where: BV_t = book value of the firm's equity at date t.

E_t = earnings for period (t-1, t)

DIV_t = dividends, net of capital contributions at date t.

The following net interest relation (NIR) is assumed (Feltham and Ohlson, 1995) :

$$I_t = (R_F - 1) F A_{t-1} \quad [NIR] \quad [9]$$

Where: $F A_{t-1}$ = financial assets, net of financial obligations, date t-1.

I_t = interest revenues, net of interest expenses, (t-1, t).

R_F = one plus the risk free interest rate.

The financial assets relation (FAR) is depicted as:

$$F A_t = F A_{t-1} + R_t - (DIV_t - CF_t) \quad [FAR] \quad [10]$$

Where: CF_t = cash flows realized from operating activities, net of investments in those activities, date t.

Financial activities take place during the period (t -1, t), with a stock of financial assets $F A_{t-1}$ which in the said time period earns interest I_t . Dividends minus cash flows reduce the total financial assets at the end of the period, but do not affect the interest gained during the period.

Operating assets, include all assets that do not generate interest earnings in the manner depicted by the [NIR] relation (e.g. cash held for operating purposes, accounts receivable, inventory, property, plant and equipment net of depreciation, accounts payable and accrued wages). Thus, operating earnings consist of all non-interest items (e.g. sales, cost of goods sold, selling and administration expenses, etc).

$$O A_t = O A_{t-1} + E_{op,t} - CF_t \quad [OAR] \quad [11]$$

Where: OA_t = operating assets, net of operating liabilities, date t .

Eop_t = operating earnings for period $(t-1, t)$

OAR: Operating assets relation

The OAR and FAR taken together, describe the firm's overall activity.

The analysis as presented above, describes a setting in which the accounting variables depict the firm's contemporaneous activity i.e. the accounting information generating process resulting from the wealth generating process.

However, in order to investigate the relation of this financial information with the firm's market value, a framework describing the arguments of the firm's market value function, must also be constructed.

The standard neoclassical models of security valuation described earlier assert that the market value of the firm's equity is determined by the net present value of the expected dividends that will be distributed to equity holders. Consistent with Feltham and Ohlson (1995), and Ohlson (1995), this is described as the basic market value relation. In this model, Ohlson (1995) assumes an economy with neutrality and homogeneous beliefs. Under those assumptions, the market value of the firm equals the present value of future expected dividends. Given further that the interest rates satisfy a nonstochastic and flat term structure, the aforementioned assumption reduces to the following model⁸.

$$P_t = \sum_{\tau=1}^{\infty} R_F^{-\tau} E_t[D_{t+\tau}] \quad \text{[PVR]} \quad [12]$$

where: PVR: present value relation

The above expression represents the current value of wealth that will be distributed from

⁸ Later on in this section we relax the aforementioned assumptions and we take into consideration risk factors.

the firm to its shareholders via the firm's dividends. The wealth generating relations are given by FAR, OAR, and NIR. Since the distribution of wealth encompasses its creation then by combining PVR, FAR, OAR, and NIR we should derive the relationship that underlies the firm's market value with its financial information.

From NIR: $I_t = (R_F - 1) FA_{t-1}$, interest revenues (i.e. I_t) from undistributed cash flows (i.e. FA_{t-1}), add to financial assets since from FAR:

$$FA_t = FA_{t-1} + R_{t-} (DIV_t - CF_t). \quad [13]$$

Combining the two we get:

$$DIV_t = CF_t + R_F \cdot (FA_{t-1} - FA_t) \quad [14]$$

Where the left hand side is the wealth distributed and the right hand side is the wealth created at time t .

$$\text{As } R_F = (1 + r_f) \Rightarrow R_F FA_{t-1} = FA_{t-1} + r_f FA_{t-1} = FA_{t-1} + FA_t$$

[15]

Thus,

$$DIV_t = CF_t + FA_{t-1} \quad [16]$$

Hence, provided that $R_F E_t[FA_{t+\tau}] \rightarrow 0$, as $\tau \rightarrow \infty$ 9, then:

$$\sum_{\tau=1}^{\infty} R_F^{-\tau} E_t[D_{t+\tau}] = FA_t + \sum_{\tau=1}^{\infty} R_F^{-\tau} E_t[CF_{t+\tau}] \quad [17]$$

Thus, using the NIR equation [9] and the FAR in equation [10], it is derived that the PV of expected dividends equals the PV of financial assets plus the PV of the expected cash flows from operations.

In order to analyse the determinants of the book value of operating assets, the clean surplus relation (CSR equation 8) is reconsidered. According to the CSR equation 8, incorporating a

9 If the firm has a finite life span i.e. T , then at $t \geq T$, $FA_t = 0$, and at $t > T$, $D_t = CF_t = 0$.

measure of future expected profitability bridges the gap between the book and market values.

CSR implies:

$$BV_t = BV_{t-1} + E_t - DIV_t \Rightarrow DIV_t = E_t + BV_{t-1} - BV_t \quad [18]$$

Defining abnormal earnings as: $AE_t = E_t - (R_F - 1) BV_{t-1}$, where $(R_F - 1) BV_{t-1}$ measures the normal earnings for period $(t-1, t)$. Then the CSR becomes:

$$DIV_t = AE_t + R_F BV_{t-1} - BV_t \quad [19]$$

Considering the future sequence of dividends, we get:

$$\sum_{\tau=1}^{\infty} R_F^{-\tau} E_t [D_{t+\tau}] = BV_t + \sum_{\tau=1}^{\infty} R_F^{-\tau} E_t [AE_{t+\tau}] \quad [20]$$

provided that $R_F E_t [BV_{t+\tau}] \rightarrow 0$, as $\tau \rightarrow \infty$. Thus the PV of the expected dividends equals the book value of the firm's asset plus the PV of the expected abnormal earnings (Feltham and Ohlson, 1995, Fama and French, 1998).

Using the same principles, by firstly defining abnormal operating earnings, I can model the relation between financial and operating activities. Abnormal operating earnings are defined as:

$$AEop_t = Eop_t - (R_F - 1) OA_{t-1} \Rightarrow Eop_t = AEop_t + (R_F - 1) OA_{t-1} \quad [21]$$

$$\text{and since OAR is: } OA_t = OA_{t-1} + Eop_t - CF_t \Rightarrow CF_t = OA_{t-1} + Eop_t - OA_t \quad [22]$$

combining the two equation [21] and [22] we get:

$$CF_t = AEop_t + R_F OA_{t-1} - OA_t \quad [23]$$

and considering the discounted future sequence of cash flows, operating earnings and operating assets it follows that:

$$\sum_{\tau=1}^{\infty} R_F^{-\tau} E_t [CF_{t+\tau}] = OA_t + \sum_{\tau=1}^{\infty} R_F^{-\tau} E_t [AEop_{t+\tau}] \quad [24]$$

provided that $R_F E_t [OA_{t+\tau}] \rightarrow 0$, as $\tau \rightarrow \infty$.

By definition we know that $BV_t = FA_t + OA_t$. Thus adding FA_t to both sides of [24] we get:

$$\begin{aligned} \sum_{\tau=1}^{\infty} R_F^{-\tau} E_t[CF_{t+\tau}] + FA_t &= OA_t + FA_t + \sum_{\tau=1}^{\infty} R_F^{-\tau} E_t[AEop_{t+\tau}] \\ \Rightarrow \sum_{\tau=1}^{\infty} R_F^{-\tau} E_t[CF_{t+\tau}] + FA_t &= BV_t + \sum_{\tau=1}^{\infty} R_F^{-\tau} E_t[AEop_{t+\tau}] \end{aligned} \quad [25]$$

and substituting into [17]:

$$\sum_{\tau=1}^{\infty} R_F^{-\tau} E_t[D_{t+\tau}] = FBV_t + \sum_{\tau=1}^{\infty} R_F^{-\tau} E_t[AEop_{t+\tau}] \quad [26]$$

Thus assuming financial relations CSR, NIR, FAR, and OAR we get equations [17], [20] and [26]. Since by PVR:

$$P_t = \sum_{\tau=1}^{\infty} R_F^{-\tau} E_t[D_{t+\tau}] \quad [27]$$

then from [17], [20] and [26] we finally get:

$$P_t = FA_t + \sum_{\tau=1}^{\infty} R_F^{-\tau} E_t[CF_{t+\tau}] \quad [28]$$

$$P_t = BV_t + \sum_{\tau=1}^{\infty} R_F^{-\tau} E_t[AE_{t+\tau}] \quad [29]$$

$$P_t = BV_t + \sum_{\tau=1}^{\infty} R_F^{-\tau} E_t[AEop_{t+\tau}] \quad [30]$$

Equation [28] states that the value of equity can be expressed as a function of its earnings and its book value. Collins, Maydew and Weiss (1997) use this theoretical framework in order to investigate the systematic relevance of earnings and book values over time. In order to test empirically the relation described by equation [28] they conduct regression analysis using the model:

$$P_{it} = a_0 + a_1 EPS_{it} + a_2 BV_{it} + e_{it} \quad [31]$$

where P_{it} is the price of a share of firm i three months after year end t ; EPS_{it} is the earnings per

share of firm i during the year t ; BV_{it} is the book value per share of firm i at the end of year t ; and e_{it} is the other value relevant information of firm i for year t orthogonal to earnings and book value.

Taking equation [29] and rearranging, we get:

$$P_t - BV_t = \sum_{\tau=1}^{\infty} R_F^{-\tau} E_t[AE_{t+\tau}] \quad [32]$$

This expression as discussed earlier, tells us that the difference between a firm's market price and its book value must reflect expectations about the future profitability of the firm.

In order to get the above expression [32] we considered an economy with risk neutrality and homogeneous beliefs (see Ohlson, 1995). However, in order to allow for risk we can replace the discount factor R_F with some factor r , which adjusts R_F for risk. That is, $r = R_F + \text{risk premium}$. A firm's cost of equity capital or the expected market return, determines the parameter r . For example, CAPM implies that $r = R_F + \text{beta} * [\text{expected return on the market portfolio} - R_F]$ [see Ohlson, 1995].

$$P_t - BV_t = \sum_{\tau=1}^{\infty} r^{-\tau} E_t[AE_{t+\tau}] \quad [33]$$

Thus, the aforementioned relation can be expressed in a form suitable in order to enable us to use it for regression analysis purposes. That is:

$$P_t - BV_t = e \Rightarrow P_t = BV_t + e \quad [34]$$

The present theoretical framework proceeds from the above expression (see also Easton and Harris, 1991). For an individual firm j , its book value (BV_j) and market value (P_j) indicate the level of wealth of the firm's equity holders. Thus, both these variables measure the stock value of the shareholders equity. Expressing this relationship for a single period t we have:

$$P_{jt} = BV_{jt} + e_{jt} \quad [35]$$

The difference between the two variables (i.e. e_{jt}) in the above equation may arise as a result of certain information not incorporated in the accounting variables but reflected in the firm's share price, i.e the future profitability of the firm.

Over time, the dynamic processes of the above mentioned variables solely depend on how the firm's earnings and market prices will evolve over time. As in a single period the firm's book value and market values are related, it follows that the single period earnings (divided by beginning of period price) should be associated with stock returns. For a single period, the deviation of the firm's book value from the previous period is a function of that period's earnings and dividends i.e.

$$\Delta BV_{jt} = E_{jt} - DIV_{jt} \quad [36]$$

and since

$$\Delta P_{jt} = \Delta BV_{jt} + e'_{jt} \quad [37]$$

It follows that

$$\Delta P_{jt} + DIV_{jt} = E_{jt} + e'_{jt} \quad [38]$$

and dividing by the price at the beginning of the return period I get:

$$(\Delta P_{jt} + DIV_{jt}) / P_{jt-1} = E_{jt} / P_{jt-1} + e''_{jt} \quad [39]$$

Prices for empirical valuation purposes are expressed as a multiple of earnings, i.e.

$$P_{jt} = aE_{jt} + e_{jt} \quad [40]$$

The above expression is an earnings based valuation model in a form that can be empirically tested. The value of the coefficient 'a' would be the outcome of a regression using

data for firm's or firms' prices and earnings for different time periods. The coefficient 'a' is the so called 'earnings response coefficient' assuming that the stock price levels are linearly related to the earnings levels.

Following the theoretical framework Ohlson (1995) and Ohlson and Feltham (1995) if a dividend is paid on security j at the time t, then equation [40] transforms to equation [41] (where all the variables are also divided by the prices at the beginning of the period):

$$P_{jt} + DIV_{jt} = aE_{jt} + e_{jt} \quad [41]$$

Taking changes instead of levels I get:

$$\Delta P_{jt} + DIV_{jt} = a\Delta E_{jt} + e''_{jt} \quad [42]$$

Note that in equation [41] it is assumed implicitly that at t-1 no dividends have been paid.

Hence from [40] I get:

$$(P_{jt} + DIV_{jt}) / P_{jt-1} = a(E_{jt} / P_{jt-1}) + e'_{jt} \quad [43]$$

Equation [43] tells us that from an earnings valuation perspective, earnings level will be associated with returns. The returned variable $(\Delta P_{jt} + DIV_{jt}) / P_{jt-1}$ can be obtained from equation [43] by subtracting 1 from each side:

$$\begin{aligned} (P_{jt} + DIV_{jt}) / P_{jt-1} - 1 &= a(E_{jt} / P_{jt-1}) - 1 + e''_{jt} \\ \Rightarrow (P_{jt} + DIV_{jt} - P_{jt-1}) / P_{jt-1} &= a(E_{jt} / P_{jt-1}) - 1 + e''_{jt} \\ (\Delta P_{jt} + DIV_{jt}) / P_{jt-1} &= (aE_{jt} - P_{jt-1}) / P_{jt-1} + e''_{jt} \\ (\Delta P_{jt} + DIV_{jt}) / P_{jt-1} &= E_{jt} / P_{jt-1} + e'''_{jt} \end{aligned} \quad [44]$$

Equation [44] holds, if

$$E_{jt} = (a-1)^{-1} P_{jt-1}$$

$$\Rightarrow aE_{jt} - P_{jt-1} = E_{jt} \quad [45]$$

From [42] we get:

$$(\Delta P_{jt} + \text{DIV}_{jt}) / P_{jt-1} = a(\Delta E_{jt} / P_{jt-1}) + e''_{jt} \quad [46]$$

Combining equation [44] and [46] we get:

$$(\Delta P_{jt} + \text{DIV}_{jt}) / P_{jt-1} = k a(\Delta E_{jt} / P_{jt-1}) + (1-k)(E_{jt} / P_{jt-1}) + e_{jt} \quad [47]$$

where k is a factor for weighting the contribution of change in earnings versus earnings levels in the explanation of stock returns.

In the empirical part I will examine the value relevance of both earnings levels and changes. The models that I will test are based on the theoretical framework that results in equation [44] (for the case of levels), equation [42] (for the case of changes), and equation [47] (for the case of levels and changes). Thus the corresponding regressions are of the form:

$$R_{jt} = a_0 + a_1(E_{jt} / P_{jt-1}) + u_{it} \quad [48]$$

$$R_{jt} = b_0 + b_1(\Delta E_{jt} / P_{jt-1}) + u'_{it} \quad [49]$$

$$R_{jt} = c_0 + c_1(E_{jt} / P_{jt-1}) + c_2(\Delta E_{jt} / P_{jt-1}) + u''_{it} \quad [50]$$

where

$$R_{jt} = (\Delta P_{jt} + \text{DIV}_{jt}) / P_{jt-1}.$$

When the above models will be tested both levels and changes are hypothesized to have significant power in explaining security prices even when they were considered together (i.e. equation [50]).

4.1.1 Theoretical framework for modeling contextual factors

4.1.1.1 Permanent versus transitory earnings.

The theoretical framework developed in the previous section suggests that both earnings levels and changes have explanatory power when they are included simultaneously in explaining stock returns (see, also, Easton and Harris, 1991; Fama and French, 1995, 1998). Ali and Zarowin (1992), also point out that many financial studies used earning changes as a proxy for unexpected earnings, following the assumption that earnings follow a random walk.

Based on these arguments, in developing the theoretical framework on the transitoriness of earnings, it is proposed that annual earnings follow an Integrated Moving Average, IMA (1,1) process, which includes both levels and changes, i.e. permits for both transitory and permanent components.¹⁰ IMA was chosen because prior theoretical and empirical evidence shows that annual earnings follow a random walk (Cheng et al., 1996; Easton and Harris, 1991). A detailed discussion that illustrates the theoretical framework for modelling contextual factors follows.

The following model is estimated:

$$AR_{jt} = b_{0t} + b_{1t}(E_{jt} - E_{jt-1}) / P_{jt-1} + b_{2t}(E_{jt} / P_{jt-1}) + u_{it} \quad [51]$$

AR_{jt} is the abnormal return (i.e. the difference of the market value of the stock price with its book value at year t minus the difference of the market value of the stock price with its book value at year t-1 divided by the difference at t-1, assuming no dividends).

Two assumptions are made in order for [51] to be valid (Ali and Zarowin, 1992, Fama and French, 2000):

1. Abnormal returns are a linear function of unexpected earnings UE_{jt} :

¹⁰ For more information about Integrated Moving Averages (IMA), see Mills (1999) and Cheng et al. (1996).

$$AR_{jt} = a_{0t} + a_{1t} UE_{jt} / P_{jt-1} + e_{it} \quad [52]$$

where a_{1t} is the earnings response coefficient.

2. Annual earnings follow an IMA(1,1) process of the form:

$$E_{jt} = E_{jt-1} + UE_{jt} - pUE_{t-1} \quad [53]$$

where p is the moving average parameter.

If earnings follow an IMA(1,1) process then unexpected earnings can be modelled as:

$$UE_{jt} / P_{jt-1} = E_{jt} / P_{jt-1} - (1-p) E_{jt-1} / P_{jt-1} - p(1-p) E_{jt-2} / P_{jt-1} - \dots \quad [54]$$

When $p=0$ then $UE_{jt} / P_{jt-1} = (E_{jt} - E_{jt-1}) / P_{jt-1}$, thus the IMA(1,1) process is a random walk.

When $p=1$ then $UE_{jt} / P_{jt-1} = E_{jt} / P_{jt-1}$, and earnings are purely transitory.

Generally p is $1 > p > 0$ and the closer p is to zero, the more permanent are earnings and the IMA(1,1) process.

For $1 > p > 0$, and taking only the first lag the model becomes:

$$UE_{jt} / P_{jt-1} = (1-p) (E_{jt} - E_{jt-1}) / P_{jt-1} - pE_{jt} / P_{jt-1} \quad [55]$$

Thus, in this theoretical framework the level and change quantities approximately define unexpected earnings. Hence, as p increases, the weight on the change variable (i.e. $1-p$ in equation [55]) decreases. Also as p increases, the weight on the change variable (i.e. p in equation [55]) increases.

If the change variable alone is used for as an approximation for the unexpected earnings the more transitory earnings are the more the higher p will be, and thus, the greater the measurement error will be as the measurement error can be viewed as:

$$UE_{jt} / P_{jt-1} - (1-p) (E_{jt} - E_{jt-1}) / P_{jt-1} = pE_{jt} / P_{jt-1} + w_{jt-1} \quad [56]$$

As a result in equation $AR_{jt} = a_{0t} + a_{1t} UE_{jt} / P_{jt-1} + e_{it}$, the inclusion of both levels and changes is expected to increase the explanatory power of the earnings response coefficient a_{1t} , if the previous year earnings are transitory. If the previous year earnings are permanent (i.e. p is

near or equal to zero) then the inclusion of levels in the modelling of unexpected earnings will not significantly increase the explanatory power of the ERC and of the model.

4.1.1.2 Framework on the earnings transitoriness and the role of the cash flows.

The issue of the time permanence of earnings has raised the stimulus in this thesis in examining also the role of operating cash flows when earnings are transitory. As Cheng, Liu and Schafer (1996) argue, earnings may contain transitory items with limited valuation implications. For example, transitory items that may be included may be current and long term accruals such as losses due to restructuring, current recognition (through asset sales) of previous (or current period's) increases in market value, one-time impact on income from changes in accounting standards, etc.

Moreover, because of compensation contracts and debt covenants are often based on reported accounting income, incentives exist for managers to introduce transitory elements in earnings. Dechow (1994) also argues that because management has some discretion over the recognition of accruals, this can be used to manipulate earnings.

Following Ali and Zarowin [1992] and Cheng, Liu and Schafer (1996), in my theoretical framework, I included both levels and changes in order to characterise the unexpected components of earnings, whereas they also include levels and changes of cash flows from operations. This is done in order to test the hypothesis that when earnings are transitory the earnings response coefficients (ERCs) on both levels and changes will have reduced significance in explaining security returns. In this situation the importance of cash flows from operations will be greater.

Thus, extending equation [51] to capture cash flows both in levels and in changes (and omitting the beginning of period price deflator for exposition purposes) I get:

$$AR_{jt} = b_{0t} + b_{1t}\Delta E_{jt} + b_{2t}E_{jt} + b_{3t}\Delta CF_{jt} + b_{4t}CF_{jt} + u_{it} \quad [57]$$

However, since the model needs to capture the incremental information of cash flows over earnings where earnings are transitory, equation [57] is modified as:

$$AR_{jt} = c_{0t} + c_{1t}\Delta E_{jt} + c_{2t}E_{jt} + c_{3t}\Delta CF_{jt} + c_{4t}CF_{jt} + c_{5t}\Delta E_{jt} D_{jt} + c_{6t}E_{jt} D_{jt} + c_{7t}\Delta CF_{jt} D_{jt} + c_{8t}CF_{jt} D_{jt} + w_{it} \quad [58]$$

where D_{jt} is a dummy variable equal to zero when $\Delta E_{jt}/P_{jt-1}$ is less than its yearly cross-sectional median and the value of one (1) when it is greater. Thus, the change in earnings to price ratio is used in order to measure the presence of transitory elements contained in the change in earnings variable.

As in Freeman and Tse (1992) and Ali (1994) transitory elements are more likely to be present when unexpected earning values are large relative to price. Hence the coefficients $c_{1t} + c_{2t}$ and $c_{3t} + c_{4t}$ represent the estimates of the earnings and cash flow response coefficients when earnings are mainly permanent. The coefficients $c_{5t} + c_{6t}$ and $c_{7t} + c_{8t}$ capture the additional information content of earnings and cash flows for firms with predominantly transitory earnings. It is expected $c_{5t} + c_{6t}$ to be negative and $c_{7t} + c_{8t}$ to be positive.

In the present study, following the aforementioned theoretical framework, I hypothesize that the incremental information content of cash flows from operations is expected to increase as the permanence of earnings decreases (see, also, Freeman and Tse, 1992; and Ali, 1994; and Cheng, Liu and Schafer, 1996). This is due to the fact that earnings may contain transitory items with limited valuation implications. Transitory items that may be included are current and long-term accruals such as losses due to restructuring, current recognition (through asset sales) of increases in market value previously (or currently), one-time impact on income from changes in

accounting standards etc. Moreover, because of compensation contracts and debt covenants are often based on reported accounting income, incentives exist for managers to introduce transitory elements in earnings.

4.1.1.3 Theoretical framework for long-return intervals

In this framework, the market return variable is considered a function of an aggregate earnings (levels) variable. A model is developed that reflects the intuition behind the hypothesized relation (Easton, Harris and Ohlson, 1992). The following notation is used to develop a model that relates a firm's earnings to its market performance for a general return interval, $(0, T)$:

- P_t = the firm's market value at date t .
- d_t = dividends paid at date t .
- R_t = $(P_t + d_t - P_{t-1})/P_{t-1}$ = market return for the $(t-1, t)$ period,
- E_t = earnings for the $(t-1, t)$ time period. and
- R_f = one plus the risk-free rate of return.

The dates run from $t = 1$ to $t = \tau$. The dependent variable measures the firm's market performance. This poses no problems for an interval $(t, t+1)$, provided that no dividends are paid between these two dates. The firm's market performance, OT return, is then determined by R_{t+1} . Extending this concept to a $(0, T)$ interval requires an assumption concerning the use of the dividends paid at dates $t = 1, \dots, \tau-1$. It is assumed that these dividends are invested in the risk-free asset. In that case the market return (dependent variable) is:

$$y_T^1 \equiv [P_T + FVS(d_1, \dots, d_{\tau-1}) - P_0] / P_0 \quad [59]$$

where

$$\begin{aligned} FVS(d_1, \dots, d_{\tau-1}) &\equiv d_1(R_F^{T-1}) + d_2(R_F^{T-2}) + \dots + d_{\tau-1}(R_F) + d_{\tau} \\ &\equiv FVS_{\tau} \end{aligned} \quad [60]$$

FV in FVS denotes future value and the S denotes a stock of value. Hence, FVS_T is the total amount an investor can withdraw at date T due to the payment and subsequent investment of dividends in the risk-free asset, and $(P_T + FVS_T)$ represents the total amount that can be withdrawn at date T . By relating this quantity to the initial market price (P_0) one obtains the market return variable Y .

The construction of the independent (earnings) variable requires an adjustment for dividends to make it consistent with the dependent (market return) variable y_T^I . The earnings variable consists of two parts, aggregate earnings over $(0,T)$ and the earnings due to the presumed investment of the dividends in the risk-free asset:

$$\begin{aligned}
 &= y_T^I \equiv [AE_T + FVF(d_1 \dots d_T)] / P_0, \\
 &\text{where} \\
 &AE_T \equiv \sum_{t=1}^T x_t, \\
 &\text{and} \\
 &FVF(d_1 \dots d_T) \equiv d_1(R_F^{T-1} - 1) + d_2(R_F^{T-2} - 1) \\
 &\quad + \dots + d_{T-1}(R_F - 1) \equiv FVF_T.
 \end{aligned}
 \tag{61}$$

FVF_T represents the earnings due to investment of dividends, FV still denotes value and an F has been appended to FV to indicate the (earnings) flow concept. $(AE_T + FVF_T)$ is the earnings that would have been earned by the firm had it not paid any dividends and instead retained this cash to invest in the risk-free asset.

The use of aggregate earnings AE_T is a central feature of the earnings variable $Z \frac{1}{T}$.

Intertemporal earnings aggregation is intrinsic and standard financial accounting embeds this attribute. (For example, four quarterly earnings add up to annual earnings, and so forth.) The

aggregation attribute of earnings has important implications. The variable AE_T measures the outcome of a firm's economic activity in terms of generally accepted accounting practice (GAAP). Though firms vary in their choice of GAAP revenue-expense rules, the argument that AX_T should be relatively insensitive to such choices for large T seems quite reasonable. For example aggregate cost of goods sold under different inventory valuation methods, i.e., FIFO and LIFO are unlikely to differ materially for, say, a ten-year interval. This aspect of GAAP and aggregation is a special case of the more general idea that most value-relevant events occurring during $(0, T)$ should be part of earnings for that period. Further, the intertemporal aggregation property of earnings makes it irrelevant in which subperiod of $(0, T)$ the value-relevant events are recognized as earnings. Of course, in reality the abstract notion of value-relevant events and their explicit accounting recognition cannot be observed separately. But this differentiation plays no role as long as, to an increasing degree, accounting earnings incorporate the events implicit in the change in market value as the return interval (T) lengthens.

Furthermore, the difference between the market value of equity at date t and the book value of equity at date t , BV_t , is called 'goodwill' g_t . Thus,

$$P_T - P_0 = \{BV_T - BV_0\} + \{g_T - g_0\} \quad [62]$$

where $g_T = \text{goodwill} = P_T - BV_T$, and $g_0 = \text{goodwill at the current period } 0$.

But in general

$$BV_1 - BV_{t-1} = E_t - d_t \quad [63]$$

This comprehensive income or clean surplus relation that was also discussed at the beginning of this chapter, implies

$$\{BV_T - BV_0\} = \sum_{t=1}^T E_t - \sum_{t=1}^T d_t = AE_T - \{FVS_T - FVF_T\} \quad [64]$$

Combining the relations, yields

$$\{P_T - P_0\} / P_0 + FVS_T / P_0 = \{AE_T + FVF_T\} / P_0 + \nabla g_T / P_0 \quad [65]$$

which reduces to

$$Y_{1/T} = Z_{1/T} + g_T^* \quad [66]$$

where

$$g_T^* \equiv \Delta g_T / P_0$$

Within this framework the *change* in goodwill captures the 'measurement error' in aggregate earnings, and, for long return intervals, it is hypothesized that the variation in the earnings variable overwhelms the variation in the earnings' error variable (g_t^*). Specifically, the correlation between Y and Z approaches one if the variance of g_t^* divided by the variance of Z approaches zero as T gets closer to x .

The basic cross-sectional regression model to be used in the present study that follows from the aforementioned theoretical framework can be expressed as in (67):

$$[MI] \quad y \frac{1}{Tj} = x \frac{1}{T} + \beta \frac{1}{T} z \frac{1}{Tj} + \varepsilon \frac{1}{Tj}, \quad [67]$$

where j denotes firm j and $\varepsilon \frac{1}{Tj}$ captures omitted factors. The subscript T emphasizes that the regression coefficients may depend on the return interval. The basic empirical analysis evaluates the hypothesis that the R^2 for M1 increases as T increases. Moreover, the model suggests that $\beta = 1$. This serves as a useful theoretical benchmark in the following sense: a dollar of additional earnings yields a dollar of additional value (Easton, Harris and Ohlson, 1992).

4.1.2 Summary on the theoretical framework

In this section I developed the theoretical framework on the value relevance of earnings and cash flows. This theoretical framework has been developed in order to be able to build up my research hypotheses. Specifically, initially I developed the theoretical framework that relates earnings and cash flows to security prices. Thereafter, I went a step further to develop a theoretical framework that ties together the level and changes of both earnings and cash flows with security returns. Since prior studies showed that the explanatory power of earnings and cash flows has been relatively low, I developed a theoretical framework for modeling contextual factors that can be used to improve further the value relevance of earnings and cash flows. Specifically, I developed a theoretical framework that relates cash flows to security prices when earnings are transitory and another framework for long-return intervals. These theoretical frameworks will be used in the next section and in the next chapter for building up my research hypotheses.

4.2 Research Hypotheses

Empirical research thus far provided evidence to support that earnings dominate cash flows in the marketplace. Existing evidence though on the incremental information content of cash flows beyond earnings has been inconclusive. The inconclusive results in prior studies, and the limited research on this issue provide motivation for this study. The research hypotheses to be tested are:

- H1: There exists a positive association between operating earnings (cash flows) and security returns in the UK, the USA and France.
- H2: Operating earnings (cash flows) are associated with security returns, given operating cash flows (earnings) in the UK, the USA and France.
- H3: The relative informativeness of operating earnings and cash flows is industry specific in the U.K, the USA and France.
- H4: The value relevance of earnings and cash flows improves as the measurement interval increases.
- H5: The value relevance of earnings and cash flows depends on the transitoriness of earnings.
- H6: The value relevance of earnings and cash flows is country specific.

A discussion on each of the above hypotheses follows.

4.2.1 Hypothesis 1: There exists a positive association between operating earnings (cash flows) and security returns in the UK, USA and France.

This research hypothesis tests the theoretical model [48] developed in this chapter. As it has already been discussed in the previous section of this chapter, the theoretical relation between earnings and cash flows with stock prices draws on the classical dividend capitalization model

and from the clean surplus relation, which implies that changes in book value are reported as either income or dividends.

As it has already been discussed in previous chapters, prior studies provided inconclusive results regarding the value relevance of earnings and cash flows (Easton and Harris, 1991; Dechow, 1994; Rayburn, 1986; Livnat and Zarowin, 1990, Bartov et al. 2001). This hypothesis predicts that operating earnings and operating cash flows are associated with security returns. In general, the following conclusions could be drawn from prior USA studies: there exists a positive association between operating earnings, operating cash flows and security returns (Charitou and Ketz, 1991). The association between operating earnings and security returns is usually greater than the association between operating cash flows and security returns (Livnat and Zarowin, 1990; Bartov et al. 2001; Charitou, 1997). Prior studies emphasized the levels of earnings and cash flows (Livnat and Zarowin, 1990; Wilson 1986, 1987; Rayburn, 1986). The present study examines both the levels and changes of operating earnings and cash flows. Regarding the empirical evidence from UK regarding this hypothesis, it is indeed very limited, with inconclusive results. More specifically, Board and Day (1989) examined the association of the levels of earnings and cash flows with security returns. The results of this UK study were weak and inconclusive regarding the usefulness of cash flows in explaining security returns. Moreover, the results from USA studies were very weak as well. The R^2 in all studies was very low.

4.2.2 Hypothesis 2: Operating cash flows (earnings) are associated with security returns, given operating earnings (cash flows) in the UK, USA, and France.

This research hypothesis tests some of the theoretical aspects of the model [50] developed in this chapter. The theoretical relation between earnings and cash flows with stock prices draws on the classical dividend capitalization model and from the clean surplus relation, which implies that

changes in book value are reported as either income or dividends. This theoretical framework was extended to take into consideration the relation between the level of stock prices and the level of book value of equity. The difference between market value and book value can result from many factors including the choice of conservative accounting practices and other information incorporated in price but not yet reflected in accounting values. The relation between the flow variables – accounting earnings and security returns – can be obtained by taking first differences in stock prices and book value of equity. By combining a book value model and an earnings model, I proposed a valuation relation in which price is a weighted function of book value, earnings and cash flows.

As it has already been discussed in previous chapters, prior studies provided inconclusive results regarding the value relevance of the level and changes in earnings and cash flows (Bartov et al., 2001; Easton and Harris, 1991; Dechow, 1994; Rayburn, 1986; Livnat and Zarowin, 1990; Charitou and Ketz, 1991). This hypothesis predicts that the levels and changes of operating earnings (cash flows) are associated with stock returns given operating cash flows (earnings). The objective of this hypothesis is: i) to provide empirical support for the propositions made by all international standard setting bodies that both earnings and cash flows play a very important role in explaining stock returns, and ii) to provide further evidence regarding the relative informativeness of operating cash flows (levels and changes) in explaining security returns, given operating earnings and thus strengthen the evidence provided by prior studies regarding the usefulness of operating cash flows. This hypothesis was tested in prior studies using USA data, with mixed and inconclusive results (Wilson, 1986; Rayburn, 1986; Bernard and Stober, 1989; Livnat and Zarowin, 1990; Charitou and Ketz, 1991). Inconclusive was also the evidence provided by those researchers who used UK data to examine the information content of cash flows beyond earnings (Board and Day, 1989; and Ali and Pope, 1995). Moreover, it should be

stressed that the explanatory power of these earnings and cash flow models was very low (Lev, 1989; Strong and Walker, 1993). In summary, the results of all prior studies are consistent with the existence of statistical association of earnings and stock returns, given operating cash flows. The empirical evidence on the association of operating cash flows beyond earnings is inconclusive.

4.2.3 Hypothesis 3: The relative informativeness of the levels and changes of operating earnings and operating cash flows is industry specific.

This research hypothesis tests some of the theoretical aspects of the model [50] developed in this chapter by taking into consideration industry specific factors. The theoretical relation between earnings and cash flows with stock prices draws on the classical dividend capitalization model and from the clean surplus relation developed in the previous section of this dissertation.

The inconclusive results of prior studies, the weak explanatory power of prior models, as well as the instability of the earnings and cash flow response coefficients led researchers to a further examination of this issue. This hypothesis predicts that operating earnings and operating cash flows are associated with security returns. Prior empirical studies which examined the usefulness of earnings and cash flows used mainly aggregate data [Bartov et al. 2001; Charitou, 1997; Livnat and Zarowin, 1990; Rayburn, 1986}. According to Lev (1989) and Cho and Jung (1991) one of the major problems of all prior studies that examined the association of operating earnings and cash flows with security returns is that they assumed that the earnings and cash flow response coefficients are constant (i.e. identical for all firms regardless of their firm-specific and industry-specific characteristics). Lev supports that the assumption made in prior studies that the response coefficients are constant, it is unrealistic. This study extends prior studies by examining the contention made by Lev and by other researchers that industry specific earnings and cash

flow information play a very important role in the marketplace. More specifically, this study hypothesizes that the relative informativeness of the levels and changes of operating earnings and cash flows is industry specific.

4.2.4 Hypothesis 4: The value relevance of earnings and cash flows improves as the measurement interval increases.

This research hypothesis tests the theoretical model [67] developed in this chapter. In this theoretical framework, the market return variable is considered a function of an aggregate earnings (levels) variable. In this framework, the difference between the market value of equity and the book value of equity at time t is called goodwill. Within this framework the change in goodwill captures the 'measurement error' in aggregate earnings, and, for long return intervals, it is hypothesized that the variation in the earnings variable overwhelms the variation in the earnings' error variable.

Thus far, there has been limited research on the value relevance i) of cash flows over long measurement intervals, and ii) of earnings and cash flows in the USA, the UK and France. Studies by Easton et al. (1992), Dechow (1994), Charitou (1997), Warfield and Wild (1992) examined the value relevance of earnings over long return intervals in the US and UK but these studies failed to examine the value relevance issue for a) both earnings and cash flows and b) for common law and code law countries.

This hypothesis predicts that the value relevance of earnings and cash flows improves in all three countries as the measurement interval is increased. Over longer measurement intervals, cash flows will suffer from fewer timing and matching problems, the importance of accruals will diminish, and therefore, earnings and cash flows are expected to converge as measures of firm performance (Dechow, 1994; Easton, Harris and Ohlson, 1992, Charitou, 1997). Cash flows

suffer more from timing and matching problems over short measurement intervals because they have no accrual adjustments and the accruals associated with cash flows are long term in nature and they do not reverse in the short-run (Dechow, 1994). On the other hand, the explanatory power of earnings compared to cash flows is expected to be the highest over short measurement intervals, because earnings include current and noncurrent accruals that mitigate the timing and matching problems related to the organization's operating, investing and financing cash flows. Prior USA and UK studies showed that there is a relative increase in the explanatory power of earnings over longer measurement intervals (Easton, et al., 1992; Charitou, 1997; Dechow, 1994).

4.2.5 Hypothesis 5: The value relevance of cash flows improves when earnings are transitory, whereas the value relevance of earnings decreases when earnings are transitory.

This research hypothesis tests the theoretical model [58] developed in this chapter. The theoretical framework developed in the previous section suggests that both earnings levels and changes have explanatory power when they are included simultaneously in explaining stock returns. Earning changes are used as a proxy for unexpected earnings, following the assumption that earnings follow a random walk. Based on these arguments, in developing the theoretical framework on the transitoriness of earnings, it is proposed that annual earnings follow an Integrated Moving Average, IMA (1,1) process, which includes both levels and changes, i.e. permits for both transitory and permanent components. IMA was chosen because prior theoretical and empirical evidence shows that annual earnings follow a random walk (Cheng et al., 1996; Easton and Harris, 1991).

This hypothesis predicts that the value relevance of earnings decreases when earnings are transitory and therefore, the value relevance of cash flows improves in all three countries when

earnings are transitory. The issue of the time permanence of earnings has raised the stimulus in the present study in examining the role of operating cash flows when earnings are transitory. As Cheng, Liu and Schafer (1996) argue, earnings may contain transitory items with limited valuation implications. For example, transitory items that may be included are current and long-term accruals such as losses due to restructuring, current recognition (through asset sales) of increases in market value previously (or currently), one-time impact on income from changes in accounting standards etc. Moreover, because of compensation contracts and debt covenants are often based on reported accounting income, incentives exist for managers to introduce transitory elements in earnings. Dechow (1994) also argues that because management has some discretion over the recognition of accruals, this can be used to manipulate earnings.

Following Ali and Zarowin (1992) and Cheng, Liu and Schafer (1996), included in the theoretical framework, both levels and changes in order to characterise the unexpected components of earnings, whereas they also include levels and changes of cash flows from operations. This is done in order to test the hypothesis that when earnings are transitory the earnings response coefficients (ERCs) on both levels and changes will have reduced significance in explaining security returns. In this situation the importance of cash flows from operations will be greater. As in Freeman and Tse (1992) and Ali (1994) transitory elements are more likely to be present when unexpected earning values are large relative to price. Hence in the model [58], the coefficients $c_{1t} + c_{2t}$ and $c_{3t} + c_{4t}$ represent the estimates of the earnings and cash flow response coefficients when earnings are mainly permanent. The coefficients $c_{5t} + c_{6t}$ and $c_{7t} + c_{8t}$ capture the additional information content of earnings and cash flows for firms with predominantly transitory earnings. It is expected $c_{5t} + c_{6t}$ to be negative and $c_{7t} + c_{8t}$ to be positive. In summary, following the aforementioned theoretical framework, I hypothesize that the incremental information content of cash flows from operations is expected to increase as the permanence of earnings decreases

(see also Freeman and Tse, 1992; Ali, 1994; and Cheng, Liu and Schafer, 1996).

Prior studies that examined earnings transitoriness include Cheng et al (1996) for the USA and Charitou et al (2000) for the UK. Prior studies have not examined the role of the cash flows when earnings are transitory in both Anglo-Saxon and code law countries.

4.2.6 Hypothesis 6: The relative informativeness of earnings and cash flows is country specific.

This research hypothesis tests the theoretical model 49 and aspects of 48 and 50 developed in this chapter, by taking into consideration country specific factors. The theoretical relation between earnings and cash flows with stock prices draws on the classical dividend capitalization model and from the clean surplus relation, which implies that changes in book value are reported as either income or dividends.

As it has already been discussed in previous chapters, prior studies provided inconclusive results regarding the value relevance of earnings and cash flows (Bartov et al. 2001; Easton and Harris, 1991; Dechow, 1994; Rayburn, 1986; Livnat and Zarowin, 1990). Furthermore, there has been very limited research examining the value relevance of earnings and cash flows in both Anglo-Saxon and code law countries. Thus, the issue of the value relevance of earnings and cash flows is still an open research question. Are earnings or cash flows valued more in Anglo-Saxon or code law countries? Are earnings or cash flows valued more in the service or manufacturing or retail industries? When the measurement interval increases, in which system, Anglo-Saxon or code law system, is there a greater increase in the value relevance of earnings and cash flows? When earnings are transitory, in which system, Anglo-Saxon or code law system, is there a greater increase in the value relevance cash flows? These research questions have not been examined in previous studies and they are still unanswered research questions in the capital

markets literature.

This hypothesis predicts that operating earnings and operating cash flows are associated with security returns. Prior studies have not examined the relative informativeness of earnings and cash flows in France, the UK and the USA. Since we showed earlier in this study that there are significant financial reporting differences between these countries, we expect that these differences will affect the value relevance of earnings and cash flows in these countries. We hypothesize that the value relevance of earnings will be the highest in France since it has the most conservative financial reporting system. On the other hand, we expect that the value relevance of earnings will be the lowest in the UK because it has the least conservative financial reporting system. Hence, we expect that cash flows will be the most value relevant in the UK and in the USA and the least value relevant in France.

4.2.7 Summary of the research hypotheses

In this section, the six major hypotheses that will be tested in this study were motivated. The first hypothesis tests whether there exists a positive association between operating earnings (cash flows) and security returns in the UK, the USA and France. The second hypothesis extends the first one by testing the value relevance of cash flows (earnings) beyond earnings (cash flows) in the UK, the USA and France. The objective of this hypothesis has been threefold: first to provide empirical support for the propositions made by all international standard setting bodies that both earnings and cash flows play an important role in the marketplace; second, to strengthen the evidence provided thus far regarding the value relevance of earnings and cash flows; and third, to provide evidence in both Anglo-Saxon and code law countries regarding the value relevance of earnings and cash flows.

The other three hypotheses, hypotheses three, four and five, test the value relevance of

earnings and cash flows by taking into consideration various contextual factors, namely, industry, measurement interval and transitoriness of earnings. The third hypothesis predicts that the value relevance of earnings is industry specific, whereas hypothesis four predicts that the value relevance and thus the explanatory power of earnings and cash flows improves as the measurement interval increases. Hypothesis five complements prior hypotheses by predicting that the value relevance of cash flows improves when earnings are transitory and vice versa. Finally, hypothesis six predicts that the value relevance of earnings and cash flows is country specific. Specifically, it is hypothesized that the value relevance of earnings will be the highest (lowest) in France (UK) since it has the most (least) conservative financial reporting system. Thus, we expect that cash flows will be the most value relevant in the two Anglo-Saxon countries and the least value relevant in the code law country, namely, France. The methodology discussed in the next chapter will be used to empirically test the six research hypotheses that were motivated in this chapter.

4.3 Notation of all variables included in the equations in the chapter

(in alphabetical order)

a = slope coefficient of a regression model

AE_t = abnormal earnings at time t

$AEop_t$ = abnormal operating earnings

AR_{jt} = the abnormal return (i.e. the difference of the market value of the stock price with its book value at year t minus the difference of the market value of the stock price with its book value at year $t-1$ divided by the difference at $t-1$, assuming no dividends).

b = slope coefficient of a regression model

BV_t = book value of the firm's equity at date t .

c = slope coefficient of a regression model

CF_t = cash flows at time t

CFO_t = operating cash flows at time t

DIV_t = dividends, net of capital contributions at date t .

d_t = dividends paid at date t .

D_{jt} = dummy or binary variable that takes the value of either 1 or 0.

e = error term

E_t = expected (permanent) earnings or earnings or operating earnings at time t

ERC = earnings response coefficient

Eop_t = operating earnings for period $(t-1, t)$

FA_{t-1} = financial assets, net of financial obligations, date $t-1$.

FVS_T = is the total amount an investor can withdraw at date T due to the payment and subsequent investment of dividends in the riskfree asset,

g = growth

I_t = interest revenues, net of interest expenses, $(t-1, t)$.

k = a factor for weighting the contribution of change in earnings versus earnings levels in the explanation of stock returns.

OA_t = operating assets, net of operating liabilities, date t .

OAR = Operating assets relation

PVR = present value relation

P_t = market value of equity at time t or stock price at year t

r = risk-adjusted discount rate

R_t = security returns for year t .

R_F = one plus the risk free interest rate.

r_f = risk free rate of interest at time t

u_{it} = disturbance or error term in a regression model

UE = unexpected earnings

Greek Notation (in alphabetical order):

ΔCF_{jt} = change in cash flows of firm j , in year t .

ΔCFO_{jt} = change in operating cash flows of firm j , in year t .

ΔE_{jt} = change in earnings of firm j , in year t .

Δg_T = change in goodwill

ΔP_{jt} = change in security price or market value of the firm j , in year t .

ρ = coefficient

CHAPTER V

STATE OF THE ART METHODOLOGIES AND TECHNIQUES EMPLOYED

This chapter discusses in more depth the following issues: a) sources of data, b) measurement of financial and market variables, c) empirical models, d) state of the art methodologies employed, and e) econometric issues.

5.1 Sources of data

The UK and French sample firms were selected from the Global Vantage research database (Standards and Poors), whereas the USA sample firms were collected from the Compustat Database (Standards and Poors). All industrial firms that have available monthly data for security returns, and available annual data for operating earnings, operating cash flows and market value of equity for the period 1987-98 will be included in the sample.

All firms included in these databases are categorized by industry (industry code is called Standard Industrial Classification, SIC). Each firm has its own code, called Global Vantage Key (GV Key) for UK and French firms, and CUSIP firm-specific code for USA firms.

TABLE 7

INDUSTRY CLASSIFICATION

Firms in all three countries are separated by industry using the Standard Industrial Classification (SIC) codes defined by Standards and Poors. The SIC categories below apply to the following industries:

SIC CODE & INDUSTRY**MANUFACTURING:**

1000-1999	Mining, construction, Oil
2000-2999	Light manufacturing industry (food products, furniture, clothing, wood products, printing, publishing)
3000-3999	Manufacturing (primary metals industry, industrial machinery, electronic equip)

RETAIL:

5000-5999	Merchandising or Retail
-----------	-------------------------

SERVICE:

7000-8999	Service
-----------	---------

All industrial firms that belong in the Manufacturing Industry (SIC 100-4299, 4400-4799), Retail Industry (SIC 5000-5999) and Service Industry (SIC 7000-8999) were selected. Firms belonging in the Utilities and Financial or Banking sector were not included in the dataset due to the major laws and regulations that apply in these industries that differ substantially from other industrial firms. Industrial firms that had all the information available for the computation of operating cash flows, operating earnings and security returns were included in the sample, resulting in the following firm-year observations for the period 1987-1998: USA =36695, UK =4234 and France = 1181. Consistent with prior empirical studies, observations that were regarded as outliers were excluded from the sample, i.e. observations with absolute change in earnings/market value, absolute change in cash flows/market value, earnings/market value and cash flow/market value greater than 150%. Also observations that were in excess of three absolute studentized residuals were considered outliers and were excluded from the sample. These restrictions resulted in approximate reduction of the sample size of about 2%, which is consistent with prior empirical studies (Easton and Harris, 1991). Therefore, the final sample size used for regression analysis purposes equals to 35872 firm-year observations for the USA sample, 4178 firm-year observations for the UK sample and 1165 firm-year observations for the French sample.

Table 8 presents detailed data information for each country on an annual basis. For the USA sample there exist data from 1987 till 1998 to estimate regression models. In the latest year, 1998, there exist 4,903 firms with available data to be included in the regression models for analysis. For the period 1987-98, there exist 36,695 firm-year observations to be included in the dataset. All these firms are relatively large and belong in the major USA stock exchanges, such as New York Stock Exchange (NYSE) and American Stock Exchange (AMEX). A partial list of USA firms included in the sample is presented in the Appendix D. In addition to the names of the firms, in this appendix I present additional information for each firm such as: identification code of each firm called Global Vantage (GV) key; the industry where each firm belongs to which is identified by the Standard Industrial Classification (SIC) code; and two size measures, the market value of equity and the book value of total assets of the firm.

As far as the UK sample of firms is concerned, there are data available for earnings and cash flows from 1990 to 1998 to be used to estimate the regression models. To be able to calculate earnings and cash flow variables for the first year, i.e. 1990 data were required for the two preceding years 1988-89 since a) all earnings and cash flow variables are deflated by the market value of equity of the previous year, b) changes in variables (earnings and cash flows) require data from the prior year to be estimated, and c) the estimation of cash flow variable requires changes in working capital data, i.e. prior year's data. Table 8, presents also the number of UK firms with complete data per year for the period 1990-98. Results show that during the latest year, 1998, there are 738 firms with complete data to be included in the regression models. The total number of firm year observations for the period 1990-98 are 4234. The UK firms available in the Global Vantage are relatively large. Appendix B presents the names of all UK firms included in the sample. Moreover, in Appendix B the following information is presented for each firm: identification code of each firm called Global Vantage (GV) key; the industry

where each firm belongs to which is identified by the Standard Industrial Classification (SIC) code; and two size measures, the market value of equity and the book value of total assets of the firm. All these UK firms are included in the London Stock Exchange.

As far as the French sample of firms is concerned, there are data available to run regressions for the eight year period 1991-1998. There are 1181 firm year observations for the period 1990-98. There are 265 French firms in the Global Vantage database during the most recent year 1998. Appendix C also presents all French firms included in the sample. In this Appendix, the names of all French firms are presented together with the GV identification code of each firm, the industry where it belongs to (SIC), and two major size measures, the market value of equity and the book value of total assets.

5.2 Measurement of financial and market variables

The financial and market variables presented here were derived from the theoretical models presented in the previous chapter. To test the aforementioned models, empirical models were constructed and the model variables were selected from the Global Vantage database. They are defined as follows:

- Stock Returns (RET_{it}): The return for security i in year t was defined as cash dividends (DIV), plus capital gains (losses), divided by the market value of equity at the beginning of the fiscal year.

$$RET_{it} = (P_t - P_{t-1} + DIV_t) / P_{t-1}$$

where:

P_t = security price of the firm at the end of the fiscal year t

DIV_t = Cash dividends for the year t

Stock Returns were calculated for the 12 month period, ending three months after the

fiscal year-end.

Since the theoretical variable 'permanent earnings' is ex-ante and unobservable, it will be replaced with ex-post and observable asset flow measures. The following earnings and cash flow variables are used in the present and prior studies to proxy the theoretical variable:

Operating Earnings (E): Net profit before extraordinary items, discontinued operations, special and non-operating items.

Cash flow from operations (CFO): Operating earnings plus all non-cash expenses and revenues (non-current accruals) plus net changes in all working capital accounts related to operations, except for changes in cash, marketable securities, and debt in current liabilities (current accruals).

The difference between earnings (E) and cash flow from operations (CFO) each period is equal to all operating accruals (OA). These OA can be decomposed into long term operating accruals, i.e depreciation, amortization, deferred taxes, equity earnings, and the change in working capital ($\Delta WC = \Delta NCA - \Delta CL$), where: ΔNCA : current non-cash assets, ΔCL : change in current liabilities (Dechow, 1994).

All independent financial variables (levels and changes of earnings and cash flows) used in the statistical models are deflated by the market value of equity of the firm (P) at the beginning of the fiscal-year.¹¹

5.3 The Empirical Models

The theoretical models [48], [49], [50], [58] and [67] presented in the previous chapter will be

¹¹ . The deflation of all independent variables is common in all cross sectional valuation studies. All prior similar studies deflated the cash flow and earnings variables with the market value of the firm at the beginning of the fiscal year in order to avoid heteroscedasticity problems (see, amongst others, Ali and Pope, 1995; Belsley, Kuh and Welch; 1980, Livnat and Zarowin, 1990).

tested empirically. In the empirical models, the relationship between the levels and changes of earnings (E, ΔE) and levels and changes of cash flows (CFO, ΔCFO) with stock returns will be tested using the following statistical models:

- a. Univariate Analysis
- b. Multivariate Analysis

5.3.1 Univariate analysis

In order to examine whether investors in UK, USA and France take into consideration in their investment decisions the levels and changes of earnings and cash flows, independent of each other, the following univariate regression model will be used:

Univariate (Simple Regression) Model:

$$RET_{it} = b_0 + b_i X_i + e_i \quad (1)$$

where:

X_i : is replaced by:

E: Operating Earnings

ΔE : Change in operating-earnings

CFO: Operating cash flows

ΔCFO : Change in operating cash flows.

RET_{it} : stock return for firm i measured over a 12-month return interval ending three months after the fiscal-year-end.

b_0 : the intercept term

b_i : slope coefficient

e_i : error term

Therefore, four different simple regression models will be run for each country (USA,

UK and France) for at least during the period 1990-98. These simple regression models will be run by year for each country as well as for the aggregate data (time series - cross sectional analysis, pooled model). Furthermore, these regression models will also be run separately for each one of the five industry groups (manufacturing, retail and service industries).

Since we expect a positive association between security returns and the levels and changes of earnings and cash flows, the coefficients of these independent variables are expected to be positive and statistically significant in all three countries. However, it is not expected that the value relevance of earnings and cash flows be equal due to the financial reporting differences between the countries. There are also differences in the level of conservatism among these countries that will affect the level of significance of earnings mainly.

5.3.2 Multivariate regression models.

In order to test whether a) both the levels and changes of earnings are valued in the capital markets, b) cash flows are valued in the capital markets by investors beyond earnings, and c) both the levels and changes of cash flows are valued by investors in the market place in the UK, USA and France, the following multivariate regression models will be used:

Multivariate (multiple regression) models:

$$RET_{it} = b_0 + b_1E + b_2 \Delta E + e_i \quad (2)$$

$$RET_{it} = b_0 + b_1E + b_3 CFO + e_i \quad (3)$$

$$RET_{it} = b_0 + b_2 \Delta E + b_4 \Delta CFO + e_i \quad (4)$$

$$RET_{it} = b_0 + b_3 CFO + b_4 \Delta CFO + e_i \quad (5)$$

$$RET_{it} = b_0 + b_1E + b_2 \Delta E + b_3 CFO + b_4 \Delta CFO + e_i \quad (6)$$

where:

E: Operating Earnings

ΔE : Change in operating-earnings

CFO: Operating cash flows

ΔCFO : Change in operating cash flows.

RET_{it} : stock return for firm i measured over a 12-month return interval ending three months after the fiscal-year-end.

Model 2 tests the value relevance of both the levels and changes of earnings in the marketplace. According to Easton and Harris (1991) and Alford et al. (1993) the sum of the coefficients of the levels and changes of earnings reflects the true permanent earnings of the firm. According to these researchers, the levels of earnings may reflect growth prospects of the firm, whereas the changes in earnings may relate to the riskiness of the firm.

Since financial reporting in the Anglo-Saxon countries is capital market oriented compared to the French system which is much more conservative and code law oriented, it is expected that the sum of the coefficients of earnings for the Anglo-Saxon countries be greater than the sum of these earnings coefficients for the French firms.

Models 3 and 4 test the incremental information content of cash flows (earnings) beyond the earnings (cash flows). More specifically, model 3 relates to the information content of the levels of earnings and cash flows, whereas model 4 relates to the value relevance of the changes in earnings and cash flows. The value relevance of earnings has been established since the seminal study of Ball and Brown (1968). Since then, several researchers questioned the reliability of earnings partly because earnings are manipulated and are based on arbitrary allocations. In the past decade standard setting bodies worldwide and researchers paid more attention to cash flows, partly because cash flows cannot be manipulated by management and are not affected by arbitrary allocations. Moreover, cash flow advocates support that since organizations cannot survive without generating cash from their operations, cash flows should be valued in the

marketplace beyond earnings and thus cash flows should complement earnings in measuring firm performance. If cash flows are valued in the marketplace beyond earnings, then the coefficient of cash flows in model 2 above is expected to be positive and significant. The stronger the association of earnings with security returns, the lower the significance of cash flows will be expected. Since in Anglo-Saxon countries capital market participants pay substantial attention to earnings, other things being equal, cash flows are expected to be more value relevant in countries that have much more conservative systems, such as France. In contrast though, in France cash flow statements are not required and this may affect negatively the value relevance of cash flows in the capital markets partly because this measure is not as known to capital market participants as it is in Anglo-Saxon countries.

Model 5 tests the value relevance of the levels and changes in cash flows. It is expected that the coefficients of the levels and changes of cash flows be positive and statistically significant if they are valued by investors in the marketplace. In all three countries, it is expected that cash flows will be valued in the marketplace.

Model 6 includes all four independent variables (both levels and changes of earnings and cash flows). This model tests whether the level and changes of earnings (cash flows) are valued beyond cash flows (earnings) in the marketplace. Prior studies in the USA and in the UK established an association between earnings and security returns, but the results regarding the value relevance of cash flows beyond earnings have been inconclusive. As far as the value relevance of cash flows beyond earnings in France is concerned, there has been no empirical evidence thus far. If cash flows (earnings) are valued by investors beyond earnings (cash flows) then the coefficients of these variables are expected to be positive and statistically significant.

Since additional hypotheses will be tested in the present study that relate to industry-differences, permanent vs transitory earnings and long windows, the above models will be

examined further. Specifically , in order to test for industry differences, the firms will be broken down into homogeneous groups according to their standard industrial classification (SIC code).

Specifically, firms in all three countries will be classified by industry using the Standard Industrial Classification (SIC) codes as defined by Standards and Poors.

The SIC categories below apply to the following industries:

SIC

1000-1999	Mining, construction, Oil
2000-2999	Light manufacturing industry (food products, furniture, clothing, wood products, printing, publishing)
3000-3999	Manufacturing (primary metals industry, industrial machinery, electronic equip)
5000-5999	Merchandising or Retail
7000-8999	Services

5.3.3 Permanent vs transitory earnings models

The theoretical model [58] that was developed in the previous chapter is empirically tested in the present study. Thus, in order to investigate the role of permanence of earnings, the basic regression model that was empirically tested in the previous section will be extended to include additional dummy variables.

The following model will be tested:

$$RET_{it} = c_0 + c_1 E_{it} + c_2 \Delta E_{it} + c_3 CFO_{it} + c_4 \Delta CFO_{it} + c_5 E_{it} * D + c_6 \Delta E_{it} * D + c_7 CFO_{it} * D + c_8 \Delta CFO_{it} * D + e_{it}$$

where RET_{it} = Security returns for the year,

E_{it} = operating earnings

CFO_{it} = operating cash flows for firm i in period t,

Δ denotes the change in a variable,

e_{it} is the error term for firm i in period t

D is a dummy variable taking a value of one when earnings are transitory and zero otherwise.

Consistent with Cheng et al. (1996), two alternative definitions are used to determine D . Under one approach, D equals 1 (0) when $|\Delta E_{it}/P_{it-1}|$ is greater than (less than) its yearly cross-sectional median (Ali, 1994). Under the second approach, firms are ranked each year according to their E_{it}/P_{it-1} , placing firms with positive E_{it}/P_{it-1} into the first nine groups with equal number of firms per group and firms with negative earnings in the tenth group. Earnings are classified in the bottom two and top two groups as transitory ($D=1$) and earnings in the middle six groups as permanent ($D=0$) (Ali and Zarowin, 1992).

5.3.4 Long windows empirical models

The theoretical model [67] that was developed in the previous chapter will be empirically tested in order to examine the value relevance of earnings and cash flows when earnings are transitory. In order to test the research hypothesis which relates to the long return intervals, the dependent and explanatory variables of the following model will be re-estimated.

$$RET_{it} = b_0 + b_1 E + b_2 CFO + e_i$$

Where:

- E : operating earnings
- CFO : Cash flow from operations
- Security Returns (RET_{it}): The return for security i in year t is defined as cash dividends (DIV), plus capital gains, divided by security price at the beginning of the fiscal year.

$$RET_t = (P_t - P_{t-1} + DIV_t) / P_{t-1}$$

where:

P_t = security price of the firm at the end of the fiscal year t

DIV_t = cash dividends for the year t

Returns will be calculated for the 12 months ending 3 months after the fiscal year-end (Easton and Harris, 1992)

More specifically, for longer measurement intervals a) the RET is the product of the annual returns over the relevant period, and b) the level of earnings and cash flows is the sum of the deflated earnings and cash flows over the relevant period.

For longer return intervals where the year T is greater than one ($T > 1$ year), the RET is the sum of the annual returns over the relevant period:

$$RET(t, T) = \sum_{i=0}^{T-1} RET_{t-i}$$

where T =return interval; t =current period.

For example, the 2-year return will be estimated as follows:

$$RET(2\text{-year}) = ((1 + RET_t) * (1 + RET_{t-1})) - 1.$$

The 3-year return will be estimated as follows:

$$RET(3\text{-year}) = ((1 + RET_t) * (1 + RET_{t-1}) * (1 + RET_{t-2})) - 1.$$

For longer than three-year return intervals, the above procedure will be followed.

5.4 State of the art methodologies employed.

One of the major advantages of this dissertation is that it combines the state of the art methodologies and techniques with international capital market research in order to examine the value relevance of earnings and cash flows. More specifically, it examines the value relevance of earnings and cash flows in both common law (USA and UK) and Code law (France) countries by

taking into consideration the following methodologies and techniques: a) Level versus changes of earnings and cash flows (Easton and Harris, 1991), b) Long windows (Easton, Harris and Ohlson, 1992), and c) permanence of earnings and the role of cash flows (Cheng, Lian and Schafer, 1996). In this dissertation, I draw on prior studies by extending and combining their contributions in different financial reporting environments. To the best of my knowledge, no previous studies have attempted to do these extensions in order to examine in that depth the role of earnings and cash flows in explaining security returns.

Since in my dissertation I extended and use various methodologies simultaneously, I expect my results to be robust with regards to the value relevance of earnings and cash flows. Namely, the methodologies employed are: a) levels versus changes of earnings and cash flows, b) long return windows, c) earnings permanence, and d) industry effects. All above methodologies were applied to two sets of financial reporting systems, namely, common law and code law. A more in depth discussion and critical evaluation of the aforementioned methodologies, and a critical evaluation of the results of prior studies for each methodology follows:

5.4.1 Methodological technique based on the level and changes of earnings and cash flows.

This methodological framework which is based on the level and changes of earnings and cash flows relates these financial variables with security returns. Collins, Maydew and Weiss (1997) used this theoretical framework in order to investigate the systematic relevance of earnings and book values over time. They conduct empirical analysis using the model:

$$P_{it} = a_0 + a_1 EPS_{it} + a_2 BV_{it} + e_{it} \quad [31]$$

where P_{it} is the price of a share of firm i three months after year end t ; EPS_{it} is the earnings per share of firm i during the year t ; BV_{it} is the book value per share of firm i at the end of year t ;

and e_{it} is the other value relevant information of firm i for year t orthogonal to earnings and book value.

Taking equation [29] and rearranging, and taking into consideration risk, we get:

$$P_t - BV_t = \sum_{\tau=1}^{\infty} r_F^{-\tau} E_t[NA_{t+\tau}] \quad [33]$$

This expression as it has already explained in the chapter where I develop the theoretical framework, it tells us that the difference between a firm's market price and its book value must reflect expectations about the future profitability of the firm. This relation can be expressed in a form suitable in order to enable us to use it for regression analysis purposes. That is:

$$P_t - BV_t = e_t \Rightarrow P_t = BV_t + e_t \quad [34]$$

The theoretical framework developed in the previous chapter to test the value relevance of earnings and cash flows proceeds from the above expression by taking into consideration the methodological improvements of Easton and Harris, 1991; Ohlson, 1995; and Ohlson and Feltham, 1995. Thus, using the aforementioned methodology, I will examine prices as a function of earnings level, earnings changes and levels and changes together. The models that I will test are based on the theoretical framework that results in equation [44] (for the case of levels), equation [42] (for the case of changes), and equation [47] (for the case of levels and changes).

Thus the corresponding regressions are of the form:

$$R_{jt} = a_0 + a_1(E_{jt}/P_{jt-1}) + u_{it} \quad [48]$$

$$R_{jt} = b_0 + b_1(\Delta E_{jt}/P_{jt-1}) + u'_{it} \quad [49]$$

$$R_{jt} = c_0 + c_1(E_{jt}/P_{jt-1}) + c_2(\Delta E_{jt}/P_{jt-1}) + u''_{it} \quad [50]$$

where

$$R_{jt} = (\Delta P_{jt} + \text{DIV}_{jt}) / P_{j,t-1}.$$

When the above models will be tested both levels and changes are hypothesized to have significant power in explaining security prices even when they were considered together (i.e. equation [50]).

Prior studies examined the aforementioned models. Specifically, Easton and Harris (1991) used a sample of USA firms over a nineteen year period. Their results indicated that both the level and changes of earnings, taken together, are valued in the marketplace. However, results indicated that the level of earnings play a more important role in explaining security returns. According to Alford et al, level and changes in earnings reflect firm growth and risk, respectively. This kind of methodology was also extended by other researchers. More recently, Bartov et al (2001) tested this model for a sample of firms in code law and common law countries. Their results indicated that the level and changes of earnings and cash flows is dependent on the financial reporting system of each country. My study extends the Easton and Harris and the other similar studies in that it examines also cash flows beyond earnings in common law and code law countries. It also extends the Bartov et al (1991) study by taking into consideration not only level and changes of earnings and cash flows, but I consider the earnings permanence effect as well as the long window effect.

In summary, one of the major advantages of this kind of methodology is that it takes into consideration not only the level but also the changes of earnings and cash flows in explaining security returns. By doing that, I take into consideration the expected permanent earnings and the expected permanent cash flows in my model. As per Easton and Harris (1991), the sum of the coefficients of the level and changes of earnings approximate the expected permanent earnings of the firm that are used for valuation purposes. Even though this methodology is theoretically sound, it does not take into consideration other contextual factors, such as earnings permanence

and long window effects. That's why in my study, I start from this theoretically sound methodology and build on that in order to apply as well earnings permanence and long windows in order to get more robust results and thus verify my results.

5.4.2 Framework for modeling contextual factors related to the permanence and transitoriness of earnings.

The framework developed in the previous section suggests that both earnings levels and changes have explanatory power when they are included simultaneously in explaining stock returns (see also Easton and Harris, 1991, Fama and French, 1995, 1998). Ali and Zarowin (1992), also point out that many financial studies used earning changes as a proxy for unexpected earnings, following the assumption that earnings follow a random walk. Based on these arguments, in developing the theoretical framework on the transitoriness of earnings, I propose that annual earnings follow an IMA (I,1) process, which includes both levels and changes, i.e. permits for both transitory and permanent components.

The following model is estimated:

$$AR_{jt} = b_{0t} + b_{1t}(E_{jt} - E_{jt-1}) / P_{jt-1} + b_{2t}(E_{jt} / P_{jt-1}) + u_{it} \quad [51]$$

AR_{jt} is the abnormal return (i.e. the difference of the market value of the stock price with its book value at year t minus the difference of the market value of the stock price with its book value at year t-1 divided by the difference at t-1, assuming no dividends).

In the previous chapter I extend the above model and I provide a theoretical framework. Furthermore, extending equation [51] to capture cash flows both levels and changes (and omitting the beginning of period price deflator for exposition purposes) I get:

$$AR_{jt} = b_{0t} + b_{1t}\Delta E_{jt} + b_{2t}E_{jt} + b_{3t}\Delta CF_{jt} + b_{4t}CF_{jt} + u_{it} \quad [57]$$

However, since the model needs to capture the incremental information of cash flows over earnings

where earnings are transitory, equation [57] is modified as:

$$AR_{jt} = c_{0t} + c_{1t}\Delta E_{jt} + c_{2t}E_{jt} + c_{3t}\Delta CF_{jt} + c_{4t}CF_{jt} + c_{5t}\Delta E_{jt} D_{jt} + c_{6t}E_{jt} D_{jt} + c_{7t}\Delta CF_{jt} D_{jt} + c_{8t}CF_{jt} D_{jt} + w_{it} \quad [58]$$

where D_{jt} is a dummy variable equal to zero when $\Delta E_{jt}/P_{jt-1}$ is less than its yearly cross-sectional median and the value of one (1) when it is greater. Thus, the change in earnings to price ratio is used in order to measure the presence of transitory elements contained in the change in earnings variable.

As in Freeman and Tse (1992) and Ali (1994) transitory elements are more likely to be present when unexpected earning values are large relative to price. Hence the coefficients $c_{1t} + c_{2t}$ and $c_{3t} + c_{4t}$ represent the estimates of the earnings and cash flow response coefficients when earnings are mainly permanent. The coefficients $c_{5t} + c_{6t}$ and $c_{7t} + c_{8t}$ capture the additional information content of earnings and cash flows for firms with predominantly transitory earnings. It is expected $c_{5t} + c_{6t}$ to be negative and $c_{7t} + c_{8t}$ to be positive.

In the present study, following the aforementioned theoretical framework, I propose that the incremental information content of cash flows from operations is expected to increase as the permanence of earnings decreases (see also Freeman and Tse (1992) and Ali (1994), and Cheng, Liu and Schafer, 1996). The issue of the time permanence of earnings has raised the stimulus in the present study in examining the role of operating cash flows when earnings are transitory. As Cheng, Liu and Schafer (1996) argue, earnings may contain transitory items with limited valuation implications. For example, transitory items that may be included are current and long term accruals such as losses due to restructuring, current recognition (through asset sales) of previous' (or current period's) increases in market value, one-time impact on income from changes in accounting standards etc. Moreover, because of compensation contracts and debt covenants are often based on reported accounting income, incentives exist for managers to

introduce transitory elements in earnings. Dechow (1994) also argues that because management has some discretion over the recognition of accruals, this can be used to manipulate earnings.

Following Ali and Zarowin [1992] and Cheng, Liu and Schafer (1996), in my theoretical framework, I included both levels and changes in order to characterise the unexpected components of earnings, whereas they also include levels and changes of cash flows from operations. This is done in order to test the hypothesis that when earnings are transitory the earnings response coefficients (ERCs) on both levels and changes will have reduced significance in explaining security returns. In this situation the importance of cash flows from operations will be greater. As in Freeman and Tse (1992) and Ali (1994) transitory elements are more likely to be present when unexpected earning values are large relative to price. Hence in the model [58], the coefficients $c_{1t} + c_{2t}$ and $c_{3t} + c_{4t}$ represent the estimates of the earnings and cash flow response coefficients when earnings are mainly permanent. The coefficients $c_{5t} + c_{6t}$ and $c_{7t} + c_{8t}$ capture the additional information content of earnings and cash flows for firms with predominantly transitory earnings. It is expected $c_{5t} + c_{6t}$ to be negative and $c_{7t} + c_{8t}$ to be positive. Prior studies that tested the earnings permanence hypothesis showed that cash flows play a more important role when earnings are transitory and vice versa (see Cheng, Liao and Schaefer, 1996). These researchers used only USA firms to test their model. Since prior studies support that the informativeness of earnings and cash flows may be country specific due to differences in financial reporting and level of conservatism, I extend all prior studies by examining not only USA but also UK and France. France is considered a code law country and UK a common law country with different levels of conservatism (as per Ball et al, 2000). Moreover, I extend these studies in the following respect. I propose an alternative methodology to verify my results, which relates to the long window effect of the earnings and cash flows. This methodology was not combined in prior studies.

5.4.3 Methodology for the long return intervals

In order to get more robust results with regards to the earnings and cash flow variables, I extend the aforementioned technique by examining the effect of earnings and cash flows over long return intervals.

Why apply this technique?

Prior studies provided several explanations for the poor earnings returns association and why the estimated earnings coefficients seemed relatively small (Easton and Zmianowski, 1991 and Easton and Harris, 1991). Although the various explanations given relate to each other, distinctions are relevant because they affect motivations for improving this kind of research designs.

The framework and methodology developed here is based on two fundamental attributes of the financial reporting process that did not received the necessary attention in prior literature, a) earnings and cash flows aggregate over time, and b) errors in aggregate earnings and cash flows are likely to become relatively less important for longer periods of aggregation.

More specifically, three streams of thought of how to improve estimations of earnings-returns relations can be identified. The first deals with the earnings expectations model (Easton and Harris, 1991, Brown 1987). The second approach views earnings as a measure of true earnings plus an error (Collins and Kothari, 1989). The third approach allows imperfect earnings because not all value relevant events observed by the market will be recognized as part of earnings during the return period, and conversely, earnings include the effects of events observed by the market prior to the return period.

The approach followed in the present study tries to minimize the effects of these three problems by focusing on fundamental attributes. Since I use the level of earnings and the level of cash flows as explanatory variables for returns, measurement of earnings and cash flow

expectations is unnecessary. Most value relevant events occurring during a specific time interval should be part of the concurrent earnings and cash flows, provided that the interval is sufficiently long, since earnings aggregate over time periods, it makes no difference in which subperiod of the interval under consideration the value relevant events are recognized as earnings. Thus, of concern are only two types of errors, i) value relevant events occurring during the return interval which are recognized in earnings of subsequent periods and ii) value relevant events occurring prior to the return interval which are recognized in earnings during the interval. But, for long intervals, the two error sources should be unimportant. A simple theoretical framework is a firm whose life matches the event window perfectly, in which case no errors are present in lifetime earnings or cash flows.

To deal with the aforementioned issues, the methodology, framework and research design presented here views earnings as a measure of value changes (Easton et al, 1992). Under this framework, the market return variable is considered a function of an aggregate earnings (levels) variable. A theoretical model is developed in the previous chapter that reflects the intuition behind the hypothesized relation (see equations [59] to [67]).

The basic cross-sectional regression model to be used in the present study that follows from the aforementioned theoretical framework can be expressed as in equation [67]

$$[MI] \quad y \frac{1}{T_j} = x \frac{1}{T} + \beta \frac{1}{T} z \frac{1}{T_j} + \varepsilon \frac{1}{T_j}, \quad [67]$$

where j denotes firm j and $\varepsilon \frac{1}{T_j}$ captures omitted factors. The subscript T emphasizes that the regression coefficients may depend on the return interval. The basic empirical analysis evaluates the hypothesis that the R^2 for M1 increases as T increases. Moreover, the model suggests that $\beta =$

1. This serves as a useful theoretical benchmark in the following sense: a dollar of additional earnings yields a dollar of additional value (Easton, Harris and Ohlson, 1992)¹².

Prior studies tested the aforementioned long return interval model, among those Easton, Harris and Ohlson (1992), Dechow (1994). The results of these studies indicated that earnings over long return intervals have a much greater explanatory power. However, Easton et al tested only earnings over long return intervals for the USA. Dechow also tested cash flows over the one and four year period only for the USA. The present study extends the aforementioned studies in the following respects: First, it employs long return intervals for both level of earnings and cash flows. Second, it examines not only USA firms but also firms from different financial reporting systems, namely UK and France. As per Ball et al (2000) and Bartov et al (2001), these countries differ substantially from the USA financial reporting due to differences in conservatism and timeliness. Also, France is a code law country whereas UK and USA are common law countries. Third, I employ, in addition to the long window methodology, the earnings permanence methodology, in order to test for the robustness of my results. To the best of my knowledge, this combination of methodologies was not done in any of the previous studies.

In summary, by testing this methodology I expect to show that the value relevance of earnings and cash flows improves in all three countries as the measurement interval is increased. Over longer measurement intervals, cash flows will suffer from fewer timing and matching problems, the importance of accruals will diminish, and therefore, earnings and cash flows are expected to converge as measures of firm performance. Cash flows are expected to suffer more from timing and matching problems over short measurement intervals because they have no accrual adjustments and the accruals associated with cash flows are long term in nature and they do not

¹² For a full discussion of this framework see The theoretical framework chapter of this study and Easton et al (1992).

reverse in the short-run (Dechow, 1994). On the other hand, the explanatory power of earnings compared to cash flows is expected to be the highest over short measurement intervals, because earnings include current and noncurrent accruals that mitigate the timing and matching problems related to the organization's operating, investing and financing cash flows. To sum up, even though prior USA and UK studies showed that there is a relative increase in the explanatory power of earnings over longer measurement intervals (Easton, et al, 1992; Charitou, 1997; Dechow, 1994), there is no comparative research on the value relevance i) of cash flows over long measurement intervals, ii) of earnings and cash flows in the USA, the UK and France.

5.5 Econometric issues and statistical tests

In this section, I will discuss the major statistical tests applied in this study as well as the major econometric tests. Initially, the major statistical tests will be discussed and thereafter the major econometric tests, namely, multicollinearity and heteroskedasticity will be discussed.

A discussion of the major statistical tests applied in the study follows.

5.5.1 Statistical tests applied

5.5.1.1 Correlation (r) and coefficient of determination (R^2)

The Pearson product moment coefficient of correlation is a measure of the linear relationship between two variables x and y. It is computed (for a sample of n measurements on x and y) as follows:

$$r = SS_{xy} / (\text{Square Root of } SS_{xx} * SS_{yy})$$

where SS = error sum of squares.

A value of r near or equal to zero implies little or no linear relationship between y and x.

In contrast, the closer r is to 1 or -1, all the points fall exactly on the least squares line. The value of r is always between -1 and +1, no matter what the units of x and y are.

Another way to measure the contribution of x in predicting y is to consider how much the errors of prediction of y were reduced by using the information provided by x . This is called the coefficient of determination R^2 . The R^2 represents the proportion of the sum of squares of deviations of the y values about the mean values that can be attributed to a linear relation between y and x . Note that R^2 is always between 0 and 1, because r is between -1 and $+1$ (Kennedy, 2003; Sincich and Mendehall, 2003, Gujarati, 2003).

5.5.1.2 The t-test.

A t-test is used to test any single linear constraint.

Suppose $y = a + b_1 + b_2 + e$ and we wish to test $b_1 + b_2 = 1$. A t-test is formulated by rewriting the constraint so that it is equal to zero, in this case as $b_1 + b_2 - 1 = 0$, estimating the left hand side as $b_1^{\text{BOLS}} + b_2^{\text{BOLS}} - 1$ and dividing this by the square root of its estimated variance to form a t statistic with degrees of freedom equal to the sample size minus the number of parameters estimated in the regression (Kutner et al. 2003; Kennedy, 2003; Sincich and Mendehall, 2003, Gujarati, 2003).

The t-statistic is estimated as follows:

$$t = b_i / S_{bi}$$

Where: b_i = coefficient of the regression model

S_{bi} = standard deviation of the beta coefficient.

5.5.1.3 The F-diagnostic

Conducting t-tests on each b parameter in a model is not a good way to determine whether a model is contributing information for the prediction of the y variable (where y is the dependent variable and x is the independent variable). If we were to conduct a series of t tests

to determine whether the independent variables are contributing to the predictive relationship, we would be very likely to make one or more errors in deciding which terms to retain and which to exclude. So, if we want to test the utility of a multiple regression model, we will need a global test (one that encompasses all the b parameters). This global test is called the F -statistic and indicates that the second order model $y = b_0 + b_1 X + b_2 X^2 + e$ is useful in explaining the dependent variable y .

The F -statistic tests the following hypothesis:

$$H_0: b_1 = b_2 = \dots = b_n = 0$$

H_a : at least one of the parameters b_1, b_2, \dots, b_n is nonzero.

The F -statistic tests the global utility of the model. The statistic used to test this null hypothesis with k variables is:

$$F\text{-statistic} = [(R^2 / k) / (1 - R^2) / (n - (k + 1))]$$

Where n is the number of data points, R^2 is the coefficient of determination and k is the number of parameters in the model, not including b_0 . Thus, when H_0 is true, this F test statistic will have an F probability distribution with k degrees of freedom in the numerator and $[n - k + 1]$ degrees of freedom in the denominator. The F test statistic becomes large as the coefficient of determination R^2 becomes large (Kutner et al. 2003; Kennedy, 2003; Sincich and Mendenhall, 2003, Gujarati, 2003).

5.5.1.4 Statistical diagnostic for estimating the t-values of the sum of coefficients used for the earnings permanence models.

The t-values of the sum of coefficients used for the earnings permanence models were computed by using the formula:

$$t = (b_i + b_{ii}) / [\text{Var}(b_i) + \text{Var}(b_{ii}) + 2\text{Cov}(b_i, b_{ii})]^{1/2}$$

Where b_i and b_{ii} are the coefficients of the variables in the model, $\text{Var}(b_i)$ and $\text{Var}(b_{ii})$ are the variances of the coefficients and $\text{Cov}(b_i, b_{ii})$ is their covariance. The sum of coefficients is statistically significant if $t > t_{\alpha, n-1}$, where α is the level of significance and n is the number of observations. (Cheng et al., 1996, Kutner et al. 2003; Kennedy, 2003; Gujarati, 2003).

5.5.1.5 The Vuong z-statistic

The Vuong z-statistic is computed by using the formula (Dechow, 1994):

$$Z1 = \left(1 / \sqrt{T} \right) \sum_{j=1}^T \left(t_j / \sqrt{k_j / k_j - 2} \right)$$

Where t_j is t-statistic for industry j , k_j is degrees of freedom, and T is the number of industries (Dechow, 1994, Cheng et al., 1996, Kutner et al. 2003; Kennedy, 2003; Gujarati, 2003).

$Z2 = \text{mean t-statistic} / \text{standard deviation of t-statistics} / \sqrt{T - 1}$.

$Z1$ assumes residual independence; $Z2$ relaxes this assumption.

5.5.1.6 Statistical diagnostic for calculating means for each model.

When running cross sectional regressions for each year, then for each year there is a slope coefficient for each variable used in the model. Since in the present study there were several years of data, the mean coefficient for the whole period, for each model was calculated as follows:

Used the sum of the coefficients (b_i) of each model for each year and it was divided by the years used (eg., b_i/n). The result is the mean b_i for each coefficient. The t-statistic is given in the SPSS output from compare mean, one sample t-test (Dechow, 1994, Cheng et al., 1996, Kutner et al. 2003; Kennedy, 2003; Gujarati, 2003).

5.5.2 Multicollinearity

One of the assumptions of the classical linear regression model is that there is no multicollinearity among the explanatory variables included in the model. Multicollinearity refers to the high correlation between the independent variables of the regression model. Why does the classical linear regression model assume there is no multicollinearity among the independent variables? The reasoning is: If multicollinearity is perfect, then the regression coefficients of the independent variables X are indeterminate and their standard errors are infinite. If multicollinearity is less than perfect, then the regression coefficients, although determinate, possess large standard errors, which means the coefficients cannot be estimated with great precision or accuracy.

Which are the practical consequences of the regression models if there exists multicollinearity? If collinearity exists, then the following consequences ensue: a) Even though the ordinary least square estimators are obtainable, their standard errors tend to be large as the degree of collinearity between the variables increases, b) because of the large standard errors, the confidence intervals for the relevant population parameters tend to be larger, hence the probability of accepting a false hypothesis increases, c) if multicollinearity is high, one may obtain high R^2 s, but none or very few estimated coefficients are statistically significant (ie. t -statistics tend to be insignificant).

The question that it can be raised now is: How do we test if we have multicollinearity in our regression models? One common statistical test used to check for multicollinearity is the Variance Inflation Factors (VIF) test.

where

$$VIF = 1 / (1 - R^{2*}),$$

R^{2*} : is the R^2 we get when we regress one independent variable on another independent variable in a single linear regression model.

If the VIFs are relatively high, mainly greater than 10, then there exists a multicollinearity problem (Kutner et al. 2003; Gujarati, 2003; Mills, 1999; Fama and French, 1995, 2000; Ball, Kothari and Robin, 2000).

In this dissertation, I applied this econometric test on all regression models. Evidence showed that my regression models do not have collinearity problems.

5.5.3 Heteroskedasticity

Another assumption of the classical linear regression model is that the disturbance term (error term) u_i is homoskedastic. Thus, when the variance of the error term u is not constant, then we have the heteroskedasticity problem. When heteroskedasticity is present, the Ordinary least square (OLS) estimates are still unbiased and consistent, but they are no longer efficient in small as well as large samples. In other words, in repeated sampling the OLS estimators on the average are equal to their true population values, and as the sample size increases indefinitely they converge to their true values but their variances are no longer minimum even if the sample size increases indefinitely.

Which are the practical consequences of heteroskedasticity in our regression models? a) when heteroskedasticity is present the model coefficients are not the conventional estimators of the beta coefficients, b) the variance of the beta coefficients is no longer minimum and thus the confidence intervals for the beta coefficients are wide and the tests of significance are less powerful, and c) the t-test and F-test give misleading conclusions.

How does one detect heteroskedasticity? One method of detecting heteroskedastic disturbances is to look for patterns in the residuals obtained from fitted equations. Although

heteroskedasticity is a property of the disturbances, since the disturbances are unknown, we have to treat residuals estimates of the disturbances and examine their patterns. If in two variables regression we observe a scatter of points about a sample regression line with dispersion of residuals increasing as the independent variable (X) increases, we would strongly suspect heteroskedastic disturbances with the variance of the residuals, $\text{Var}(e)$, increasing with X . Therefore, we test for heteroskedasticity using plots of our variables for each model with their residuals (squares).

Another way to test for heteroskedasticity is to use the White test of heteroskedasticity which tests if the variances of the error term are homoskedastic.

In the present study, consistent with prior empirical studies, I deflated all my dependent and independent variables with the market value of equity. By doing that, we try to avoid the problem of non-constant variances. Furthermore, the plots and the statistical tests showed that my models do not have heteroskedasticity problem. (Kutner et al. 2003; Gujarati, 2003; Mills, 1999; Fama and French, 1995, 2000; Ball, Kothari and Robin, 2000).

5.6 Summary of the methodology employed

In this chapter I discussed in depth the methodology to be employed in this dissertation in order to test the research hypotheses developed in the previous chapter. Initially, I discussed the major sources of data and the measurement of financial and market variables. Thereafter, I developed the empirical models to be used to test the major research hypotheses. These empirical models were based on the theoretical models developed in the previous chapter. Both univariate and multivariate models were developed. Thereafter, these models were extended to take into consideration the major contextual factors used in the dissertation, namely, measurement interval, transitoriness of earnings, industry and country factors. Since in order to draw the right

conclusions from these models, the estimators of the models must be best linear unbiased estimators (BLUE), I conducted various statistical and econometric tests, among those, heteroskedasticity and multicollinearity tests. The empirical results that will be discussed in the next chapter will be based on the methodology discussed in this chapter.

CHAPTER VI

EMPIRICAL RESULTS

6.1 Introduction

The research hypotheses discussed earlier in Chapter IV are tested in what follows empirically.

More specifically, the following empirical results are presented:

- a. Regression Diagnostics:
 - 1. Descriptive Statistics
 - 2. Correlation Analysis
- b. Regression Analysis:
 - 1. Empirical results of the value relevance of Earnings and cash flows
(Research hypotheses 1 and 2):
 - Univariate Analysis for the UK, the USA and France;
 - Multivariate Analysis for the UK, the USA and France.
 - 2. Industry specific empirical results of the value relevance of Earnings and cash flows (Research hypothesis 3).
 - 3. Empirical results of the value relevance of Earnings and cash flows, i.e. the case of long measurement intervals (Research hypothesis 4).
 - 4. Empirical results of the value relevance of Earnings and cash flows when earnings are transitory (Research hypothesis 5).
 - 5. Country specific empirical results of the value relevance of Earnings

and cash flows in the UK, the USA and France (Research hypothesis 6).

Table 8 (already presented earlier in chapter V) cites the dataset of all firms to be used for each country examined. Specifically, Panel A presents the annual dataset for the USA firms. All the data available in the Compustat database were collected for the USA. The total number of observations for the period 1987-98 were 36,695 firm year observations. Panel B presents the annual dataset for the UK firms. All data available in the Global Vantage Database by Standards and Poors for the UK were 4,234 firm year observations for the period 1990-98. Finally, panel C presents the annual dataset for the French firms. All data available in the Global Vantage Database by Standards and Poor for France were 1,181 firm year observations for the period 1990-98.

Statistical analysis for the above datasets was conducted in this study. A critical analysis and discussion of all models tested is presented in this chapter.

6.2 Regression diagnostics

In this part I discuss, analyse and critically evaluate the descriptive statistics and correlation analysis results.

6.2.1 Descriptive statistics

Table 9 presents descriptive statistics for all the earnings, cash flows and security returns variables examined in the study for all three countries (USA, UK and France) for the period 1987-1998. Results show that 35873, 4178 and 1165 firm-year observations were available to be used in the analysis for the USA, the UK, and the French dataset, respectively. Consistent with prior studies, extreme observations of each of the earnings and cash flow variables were excluded from the analysis.

As it has already been hypothesized earlier in this dissertation, I expect differences in the value relevance of earnings and cash flows with security returns. These descriptive analysis results will provide an indication as to whether there exist differences in financial reporting among countries. As discussed earlier in the study, we expect differences in the level of earnings due to the fact that there are financial reporting differences between these countries, which is also reflected in the different level of conservatism that exists in each countries' system. More specifically, the results indicate the following: a) the mean security return for UK and USA is the highest (0.092 and 0.08, respectively), whereas in France is somewhat lower, 0.055, b) the mean earnings level is higher for UK (0.057) and lowest for USA. For the French dataset the mean of earnings levels is 0.037; c) the mean of the cash flow levels is shown to be the highest for the French dataset (0.184) and lower for UK and USA (0.123 and 0.057, respectively); d) as expected the standard deviation of the levels and changes of cash flows is always higher than the level and changes of earnings in all three countries. These results are consistent with the results

provided in prior empirical studies.

6.2.2 Correlation analysis

Table 10 presents Pearson correlation results for all dependent and independent variables used in the study, namely, security returns (RET), levels and changes of earnings (E and ΔE) and levels and changes of cash flows (CFO and ΔCFO). As it has been hypothesized, I expect differences in the value relevance of earnings and cash flows in different countries. Research questions like the following have been unanswered in the literature and this correlation analysis is expected to provide an initial indication as to the value relevance of earnings and cash flows. Are earnings or cash flows valued more in Anglo-Saxon or code law countries? Are earnings or cash flows valued more in the service or manufacturing or retail industries? When the measurement interval increases, in which system, Anglo-Saxon or code law system, is there a greater increase in the value relevance of earnings and cash flows? When earnings are transitory, in which system, Anglo-Saxon or code law system, is there a greater increase in the value relevance cash flows?

The results show the following: a) as expected the correlation between the level and changes of earnings and security returns is higher than the correlation between cash flows and security returns. This is partly due to the fact that security analysts, investors and creditors have traditionally emphasized earnings, b) as expected, the correlation between earnings and cash flows is higher in the UK and the USA than in France. This is due to the fact that the French financial reporting system is more closely aligned to the tax system, c) the correlation between security returns and the levels of earnings is the highest in all three countries, whereas the correlation between security returns and changes in cash flows is again consistently the lowest in all three countries.

6.3 Regression analysis results

In this part regression analysis results that relate to the test of all research hypotheses are presented, analysed and critically evaluated.

6.3.1 Univariate and multivariate regression analysis results on the value relevance of earnings and cash flows for the USA, UK and France.

Research hypothesis 1 predicts that there exists a positive association between operating earnings (cash flows) and security returns in the UK, the USA and France. Thus, I expect differences in the value relevance of earnings and cash flows between Anglo-Saxon and code law countries. More specifically, it was hypothesized that a) earnings and cash flows are value relevant in all countries and b) earnings will be more value relevant than cash flows in all countries. The univariate results presented in Table 11 in this section do support the above hypotheses. Specifically, these univariate results indicate the following. First, as far as the value relevance of earnings is concerned, as expected, the results indicate that both the levels and changes in earnings are positive and statistically significant in all three countries. Interestingly, the size of the levels of earnings and the size of the changes in earnings is approximately equal in all three countries, in spite of the fact that the French financial reporting system is much more conservative. Specifically, the coefficients of the level of earnings are 0.759, 0.767 and 0.793 for the USA, the UK, and France, respectively. The coefficients of the changes in earnings are 0.701, 0.612 and 0.669, for the US, UK and France, respectively. As far as the R^2 is concerned, results indicate that French earnings (levels and changes) are more value relevant than the earnings in the USA and the UK, even though the financial reporting system in France is more conservative. The R^2 for the level of earnings is 11.20%, 8.80% and 6.70% for France, the UK and the USA. The same ranking applies to the changes in earnings, although the R^2 is somewhat lower,

indicating that the level of earnings is more value relevant than the changes in earnings.

As far as the value relevance of cash flows is concerned, as expected, results indicate that cash flows are value relevant in all three countries. All the coefficients of the levels and changes in cash flows are positive and statistically significant. The size of the coefficients of cash flows as well as the magnitude of the R^2 are somewhat higher in the Anglo-Saxon countries, suggesting that cash flows could be less value relevant in France. Moreover, as it was expected the size of the earnings coefficients and the magnitude of the R^2 are relatively higher than the equivalent cash flow statistics. These results are consistent with my hypotheses, expectations and consistent with prior empirical evidence. This is due to the fact that earnings are considered more value relevant in the stock markets.

Table 12

Multivariate analysis regression results for all years tested for all firms for the USA, UK and France.

Where E: operating earnings, ΔE : Changes in earnings, CFO: Operating cash flows, ΔCFO : changes in Operating Cash flows; RET: annual security returns. All Independent variables (E, ΔE , CFO, ΔCFO) are deflated by the market value of the firm at fiscal year end of the previous year.

6.3.1.1 Results related to the level and changes in earnings.

Table 12 (model a) tests the value relevance of both the level and changes of earnings. I expect the coefficients of these variables to be positive and statistically significant. Moreover, the sum of these coefficients is expected to be close to unity and to approximate the true coefficient of the permanent earnings (Easton and Harris, 1991). If these earnings coefficients are positive, it means that investors perceive increases in operating earnings as good news and any increases in the firm's earnings are expected to increase stock prices.

Consistent with my hypothesis, all the coefficients of the levels and changes in earnings are positive and statistically significant. The sum of these coefficients is positive and statistically significant and it is close to unity for all three countries. As far as the R^2 is concerned, it is relatively higher in France (14.3% vs 10% and 8.4% in the UK and in the USA, respectively) even though financial reporting in France is code-law oriented and it is more conservative. Moreover, the F-value of all models in the USA, the UK and France is relatively high and statistically significant as it is supported by the p-value of the models (p-value in all models is 0.000, supporting strong statistical significance).

6.3.1.2 Results related to the level and changes in cash flows.

As far as the value relevance of the levels and changes in cash flows is concerned (model b, table 12), it is expected that the coefficients be positive and statistically significant. If these coefficients are positive, it means that investors perceive increases in operating cash flows as good news and any increases in the firm's cash flows are expected to increase stock prices. The results indicate that the sum of these coefficients is indeed positive and statistically significant, indicating that cash flows are valued positively in the marketplace by investors. The R^2 of the models is higher in the UK and lowest in France, indicating that cash flows are not valued as

much in France as they are valued in the UK. Moreover, the F-value of all models in the USA, the UK and France is relatively high and statistically significant as it is supported by the p-value of the models (p-value in all models is 0.000, supporting strong statistical significance).

Furthermore, as it was expected both the size of the cash flow coefficients and the model's R^2 s are relatively lower than the equivalent earnings statistics presented in the same table (model a). These results, thus indicate that taken independently, earnings are valued more in the marketplace than cash flows. Again, these results are consistent with the expectations and with prior empirical evidence.

In summary, the aforementioned univariate and multivariate analysis results presented in Tables 11 and 12 are consistent with my Hypothesis 1, i.e., that the level and changes of earnings and cash flow variables are value relevant in all three countries, USA, UK and France. From the practitioner point of view, these results support that financial analysts, investors and creditors consider both earnings and cash flows in making their decisions.

Thus far, in univariate and multivariate analysis, earnings and cash flow variables were examined alone in the models. In order to examine whether investors, analysts and creditors take into consideration simultaneously both earnings and cash flows, multivariate regression analysis will be undertaken that includes all level and changes of earnings and cash flows. This analysis follows.

6.3.2 Multivariate regression analysis results on the value relevance of earnings and cash flows for the USA, the UK and France.

Research hypothesis 2 predicts that the levels and changes of operating earnings (cash flows) are associated with stock returns given operating cash flows (earnings). The objective of this hypothesis is: i) to provide empirical support for the propositions made by all international

standard setting bodies that both earnings and cash flows play a very important role in explaining stock returns, and ii) to provide further evidence regarding the relative informativeness of operating cash flows (levels and changes) in explaining security returns, given operating earnings and thus strengthen the evidence provided by prior studies regarding the usefulness of operating cash flows. This hypothesis was tested in previous studies using USA and UK data, with mixed and inconclusive results.

The multivariate regression model results presented in tables 13 to 17 are used to provide support for the research hypothesis 2. The critical analysis and discussion of the multivariate regression models tested which follows relates to: i) value relevance of cash flows (earnings) beyond earnings (cash flows) [Table 13], ii) value relevance of both levels and changes of cash flows (earnings) beyond earnings (cash flows) [Tables 13-17]. Both pooled results as well as annual results are presented in this analysis.

Table 13

Multivariate analysis regression results for all years tested for all firms for the USA, the UK and France.

MODELS WITH TWO VARIABLES

Model a: Level of earnings and cash flows: $RET = a_0 + b_1 E + b_3 CFO$

Model b: Changes of earnings and cash flows: $RET = a_0 + b_2 \Delta E + b_4 \Delta CFO$

COUNTRY	Constant	E	ΔE	CFO	ΔCFO	N	VIF	F - value	R adj
USA	0.0759 *	0.666 *		0.152 *				1350.2 *	
(a)	(25.267)	(38.126)		(10.281)		35873	1.372	[0.000]	7.00%

*, **, *** Statistically significant at $\alpha=1\%$, 5% and 10% respectively; (), Figures in parentheses represent t-statistic; [], Figures represent p-value

Where E: operating earnings, ΔE : Changes in earnings, CFO: Operating cash flows, ΔCFO : changes in Operating Cash flows; RET: annual security returns. All Independent variables (E, ΔE , CFO, ΔCFO) are deflated by the market value of the firm at fiscal year end of the previous year.

Thus far, in previous models, only the earnings or cash flow variables alone were entered in the models. In order to test the value relevance of cash flows (earnings) beyond earnings (cash flows), models (a) and (b) in table 13 were tested. Since the value relevance of earnings has been established in previous studies, I hypothesize that the coefficients of the earnings variables to be positive and statistically significant. On the other hand, although the coefficient of cash flows is expected to be again positive and significant, it is still remained an empirical question to be tested, since thus far previous studies provided inconclusive results.

As I hypothesized, all the coefficients of the levels and changes of earnings variables presented in Table 13 are positive and statistically significant. The size of the level of earnings coefficients ranges from 0.576 to 0.756. Similar results are also provided for the changes in earnings coefficients in model (b). Thus, I conclude that the value relevance of earnings in all three countries is similar., i.e. investors in all three countries pay similar attention to the earnings information in making investment decisions. As far as the incremental information content of cash flows is concerned, again all coefficients of the level of cash flow variable in model (a) are positive and statistically significant. Specifically, the coefficient of the level of cash flows is 0.072, 0.152 and 0.239 for France, the USA and the UK respectively. As it can be seen, investors and security analysts in the UK pay more attention on the operating cash flows than the investors do in France and in the USA. In contrast, investors in France pay the least attention on operating cash flows in making investment decisions. As far as model (b) is concerned, which tests the changes of cash flows, results indicate that investors in the UK pay significant attention on the changes of cash flows in making investment decisions. In summary, in UK all cash flow coefficients are positive and significant whereas in the USA and France the coefficient of the changes in cash flows are negative, indicating that lag cash flows are statistically significant in

explaining security returns. As far as the models' R^2 s is concerned, it is shown that in France it is the highest and in the USA it is the lowest. Regarding the importance of the models is concerned, the F-values are relatively high and statistically significant in all three countries. The p-value of all three models is 0.000, indicating very high statistical significance. Moreover, as far as the correlation between the variables included in the model is concerned, the Variance Inflation Factors (VIF) show that the VIFs are as expected, relatively low, indicating that the models tested do not have any collinearity problems.

Thus far, all models tested in Table 13 included two variables at a time, one earnings and one cash flow variable. In order to test how investors perceive simultaneously in their investment decisions all four variables, I will include in the model both the level and changes of earnings and cash flows. The results of the value relevance of both the levels and changes of cash flows (earnings) beyond earnings (cash flows) are presented in Table 14. It is hypothesized that the coefficients of the earnings variables be positive and statistically significant. Also the coefficients of the cash flow variables are expected to be positive and statistically significant due to the increased attention to cash flow reporting in recent years and due to the importance of cash flows in the capital markets.

Consistent with my research hypothesis, results in Table 14 indicate clearly that the levels and changes in earnings are valued by investors beyond cash flows. All the coefficients of earnings are consistent with the expectations, i.e. positive and statistically significant. The sum of the coefficients of earnings is close to unity (as expected) in all three countries. Specifically the sum of the earnings coefficients (b_1+b_2) is 1.01, 0.933, and 0.725 in France, the USA and the UK respectively. These results indicate that investors in France pay more attention on earnings in making investment decisions, compared to investors in the USA and UK. In contrast, results indicate that investors in the UK pay much less attention on earnings in making investment

decisions. This may be due to the fact that earnings in a common law country, such as the UK, are much easier to be manipulated than in a code law conservative country such as France.

Table 14

Multivariate analysis regression results for all years tested for all firms for the USA, UK and France.

MODEL WITH FOUR VARIABLES

Results for the level and changes of earnings and cash flow model: $RET = a_0 + b_1 E + b_2 \Delta E + b_3 CFO + b_4 \Delta CFO$

	VIF's		1.297	1.306	1.459	1.403	0.078	0.042			

*, **, *** Statistically significant at $\alpha=1\%$, 5% and 10% respectively; (), Figures in parentheses represent t-statistic; [], Figures represent p-valueWhere E: operating earnings, ΔE : Changes in earnings, CFO: Operating cash flows, ΔCFO : changes in Operating Cash flows; RET: annual security returns. All Independent variables (E, ΔE , CFO, ΔCFO) are deflated by the market value of the firm at fiscal year end of the previous year.

Regarding the importance of cash flows is concerned, results in Table 14 indicate that the cash flow variables are taken into consideration for investment decisions in the UK and the USA. The sum of the cash flow coefficients b_3+b_4 are 0.209, 0.091 and 0.013 in the UK, the USA and France, respectively. As it can be seen, again in the UK investors pay much more attention on cash flows compared to the investors in France. As far as the significance of the models is concerned, results indicate that the model is statistically significant as it is shown by the F-values and p-values. Specifically, the F-values of the models are 876.9, 129.5 and 49.5, for the USA, the UK and France, respectively. In all three countries, the models are highly statistically significant at $p=0.000$. As far as the explanatory importance of the models is concerned, the models' R^2 is the highest in France, and this is mainly due to the significance of earnings. Specifically, the R^2 s are 17.90%, 11.0% and 8.90% in France, the UK and the USA, respectively. These results indicate that French capital market participants take more into consideration the earnings information in making investment decision, whereas investors in the UK and in the USA do take into consideration both earnings and cash flows, but the UK and the USA markets do not value this earnings and cash flow information as the French market.

In summary, the results presented thus far in this section do support my research hypothesis 2. Specifically, the following conclusions can be drawn by testing hypothesis 2: a) that earnings are valued by investors in all three countries, b) earnings are valued more by French investors and the least by USA investors, c) cash flows are valued by investors in the UK and the USA only, given earnings, d) cash flows are valued mostly by UK investors, given earnings, e) all models in all three countries are highly statistically significant as shown by the p-value of the models, f) variability in stock prices is affected mostly in France by the variables included in the model, as it is shown by the high R^2 (17.9%). In contrast, the lowest variability in stock prices

is shown in the USA (R^2 is 8.9%), g) the models are not affected by any collinearity problems since in all three countries the Variance Inflation factors (VIF) are relatively low.

The aforementioned discussion related to all year results for all three countries. Results in Tables 15, 16 and 17 extend the results provided in Table 14. Yearly results are presented for all 3 countries for at least a nine-year period. These results confirm the evidence provided in Table 14, i.e. that earnings are strongly valued by the investors in all three countries, the USA, the UK and France. In all countries, in all years, earnings were positive and statistically significant. More specifically, as hypothesised, results in Table 15 indicate that the sum of the coefficients of the level and changes in earnings is positive and statistically significant. The average sum of those coefficients is 0.725, which means that for every sterling of increase in the earnings in the UK, it is expected that the stock price will increase by 72.5 pence. As far as the role of cash flows is concerned, results indicate that in most years tested the sum of the coefficients of cash flows b_3+b_4 is positive and statistically significant in four years. However, if we take into consideration all years together, the sum of the coefficients of cash flows is positive and statistically significant, i.e. $b_3+b_4=0.2093$. These results indicate that investors in the UK do take into consideration cash flows, in addition to earnings in their investment decisions. Specifically, for every one sterling increase in cash flows for a firm, it is expected that on average the stock price will go up by about 20 pence. Furthermore, results indicate that the UK models are statistically significant in all years tested as it is shown by the high F-values and the p-values of the model. Moreover, the mean R^2 for all years is 11% and in all years it ranges from 8.2% to 21%. As expected, these results indicate that in the UK the variation of security prices is affected by the earnings and cash flow variables. In summary, the UK results presented in Table 15 indicate that a) the level and changes of earnings are important to UK investors for investment decisions, b) cash flows are important as well to UK investors for investment decisions, c) earnings are at least

three times as important than the cash flows ($b_1+b_2=0.725$ vs $b_3+b_4=0.209$), and d) the earnings and cash flow model is statistically significant in all years tested.

*, **, *** Statistically significant at $\alpha=1\%$, 5% and 10% respectively; (), Figures in parentheses represent t-statistic; [], Figures represent p-value. Where E: operating earnings, ΔE : Changes in earnings, CFO: Operating cash flows, ΔCFO : changes in Operating Cash flows; RET: annual security returns. All Independent variables (E, ΔE , CFO, ΔCFO) are deflated by the market value of the firm at fiscal year end of the previous year.

As far as the importance of earnings and cash flows on an annual basis for the USA is concerned the results are presented in Table 16. More specifically, as it was hypothesized, results indicate that the sum of the coefficients of the level and changes in earnings is positive and statistically significant in all years from 1987-98. The average sum of those coefficients is 0.933, which means that for every dollar of increase in the earnings in the USA, it is expected that the stock price will increase by about 93 cents. As far as the role of cash flows is concerned, results indicate that in most years tested the sum of the coefficients of cash flows b_3+b_4 is positive and statistically significant in five years. However, if we take into consideration all years together the sum of the coefficients of cash flows is positive and statistically significant, i.e. $b_3+b_4=0.091$. These results indicate that investors in the USA take into consideration cash flows, in addition to earnings in their investment decisions. Specifically, for every one dollar increase in cash flows for a firm, it is expected that on average the stock price will go up by about 9 cents. Furthermore, results indicate that the USA models are statistically significant in all years tested as it is shown by the high F-values and the p-values of the model. Moreover, the mean R^2 for all years is 8.9% and in all years it ranges from 5.3% to 15%. As expected, these results indicate that in the USA the variation in security prices is affected by the earnings and cash flow variables.

In summary, these USA results presented in Table 16 do support my research hypothesis. Specifically, results indicate that a) the level and changes of earnings are important to USA investors for investment decisions, b) cash flows are important as well to USA investors for investment decisions, c) earnings are at least nine times as important than the cash flows ($b_1+b_2= 0.933$ vs $b_3+b_4= 0.091$), d) the earnings and cash flow model is statistically significant in all years tested as it is shown by the F-statistic and p-values.

Finally, as far as the importance of earnings and cash flows on an annual basis for France is concerned the results are presented in Table 17. More specifically, as it was hypothesized, results indicate that the sum of the coefficients of the level and changes in earnings is positive and statistically significant in all years from 1990-98. The average sum of those coefficients is 1.01, which means that for every Euro of increase in the earnings in France, it is expected that the stock price will increase by about one Euro. As far as the role of cash flows is concerned, results indicate that the sum of the coefficients of cash flows b_3+b_4 is not statistically significant. However, if we take into consideration all years together the sum of the coefficients of cash flows is positive and statistically insignificant, i.e. $b_3+b_4=0.0129$. These results indicate that investors in France may not take into consideration cash flows, in addition to earnings in their investment decisions. Furthermore, results indicate that the French models are statistically significant in all years tested as it is shown by the high F-values and the p-values of the model. Moreover, the mean R^2 for all years is 17.9% and in all years it ranges from 15.9% to 27.8%. As expected, these results indicate that in France the variation of the securities prices is affected mainly by the earnings variables.

In summary, the French results presented in Table 17 do support my research hypothesis. Specifically, results indicate that a) the level and changes of earnings are important to French investors for investment decisions, b) cash flows are not that important to French investors for investment decisions, beyond earnings information, c) earnings are considered far more important than cash flows ($b_1+b_2= 1.01$ vs $b_3+b_4= 0.0129$), d) the earnings and cash flow model is statistically significant in all years tested as it is shown by the F-statistic and p-values.

In summary, the results presented in Tables 14-17 are consistent with my expectations and they do support my research hypothesis 2. The following conclusions can be drawn: a) that earnings are valued by investors in all three countries, the USA, the UK, and France, b) earnings are valued more by French investors and the least by USA investors, c) cash flows are valued by investors in Anglo-Saxon countries (the UK and the USA) only, given earnings, but cash flows do not seem to be valued by French investors d) cash flows are valued mostly by the UK investors, given earnings, e) all models in all three countries are highly statistically significant as it is shown by the p-value of the models, f) variability in the stock prices is affected mostly in France by the variables included in the model, as it is shown by the high R^2 (17.9%). In contrast, the lowest variability in the stock prices from these variables is shown in the USA (R^2 is 8.9%).

Even though the above results strongly support the usefulness of earnings and cash flows in investment decisions, the results should be interpreted with caution since by using aggregate data, it may be inferred that the relationship between earnings and cash flows with stock prices is homogeneous across firms. It should be noted that the assumption that investors react identically to earnings and cash flows by all firms may not be realistic. Thus, in what follows the above models are extended to take into consideration further relevant factors.

6.3.3 Statistical analysis results related to the contextual factors.

In this section, I will extend the previous results related to the valuation of earnings and cash flows by taking into consideration additional factors that investors and security analysts may take into consideration in making investment decisions. Specifically, I will examine the following factors:

- a. Industry analysis for each country (Hypothesis 3)
- b. Analysis for longer return windows for each country (Hypothesis 4)

- c. Analysing the usefulness of earnings and cash flows for each country when earnings are transitory (Hypothesis 5)
- d. Analyzing the valuation of financial information (earnings and cash flows) by country (Hypothesis 6).

A discussion, analysis and critical evaluation of the results related to each one of the above factors tested follows.

6.3.3.1 Multivariate analysis regression results for testing the relative valuation of earnings and cash flows by industry effects for each country.

Hypothesis 3 predicts that investors in making investment decisions pay different attention to earnings and cash flows, and this depends on the industry. The inconclusive results of previous studies, their weak explanatory power, as well as the instability of the earnings and cash flow coefficients, led researchers and myself to a further examination of this issue.

This research hypothesis tests the theoretical model [50] developed in the previous chapters by taking into consideration industry specific factors. This hypothesis predicts that operating earnings and operating cash flows are associated with security returns, but the relationship is industry specific. Prior empirical studies which examined the usefulness of earnings and cash flows used mainly aggregate data. One of the major problems of previous studies that examined the association of operating earnings and cash flows with stock prices is that researchers assumed that the earnings and cash flow coefficients are the same for all firms regardless of the industry they belong to. However, researchers support that the assumption made in previous studies that investors are not affected by industry factors, it may not be that realistic. The results that follow extend previous studies by examining the contention made by researchers that earnings and cash flow information is industry specific. More specifically, hypothesis 3 supports that the relative

valuation of the levels and changes of operating earnings and cash flows is industry specific.

Table 18 presents results for all years for all three countries for three major industrial sectors. These industrial sectors are: a) manufacturing, b) retail, and c) service. As per Standards and Poors, firms are classified by industry by taking into consideration a Standard Industrial Classification (SIC) code. Firms with SIC code from 100 to 4999 are classified as manufacturing, firms with SIC code from 5000 to 5999 are classified as retail, and finally, firms with SIC code from 7000 to 8999 are classified as service organizations. Clearly, these type of industries have different financial characteristics. For example, manufacturing firms are more capital intensive compared to retail and service organizations. Capital intensiveness may lead to a greater need for cash flows for reinvestment purposes. Moreover, manufacturing firms have greater depreciation expenses and thus the difference between earnings and cash flows in manufacturing firms may be greater when compared to the retail and service firms. Furthermore, manufacturing and retail firms are expected to maintain higher inventory levels compared to service organizations. This difference in the inventory levels may lead to greater differences between earnings and cash flows in these two industries if there are great variations in inventory levels from year to year. For example, great increases in inventory levels in one year, assuming cash was used to manufacture or acquire this inventory, will lead to a reduction in cash flows.

*, **, *** Statistically significant at $\alpha=1\%$, 5% and 10% respectively; (), Figures in parentheses represent t-statistic;

Where E: operating earnings, ΔE : Changes in earnings, CFO: Operating cash flows, ΔCFO : changes in Operating Cash flows; RET: annual security returns.

All Independent variables (E, ΔE , CFO, ΔCFO) are deflated by the market value of the firm at fiscal year end of the previous year.

Specifically results in Table 18 indicate the following. First, as hypothesized, the level of earnings variables is statistically significant in all industries in all countries. In all three countries, the earnings coefficient is the highest in the retail industry (0.63, 0.512. and 1.27 for the UK, the USA and France, respectively). As far as the changes in earnings is concerned, results indicate that it is always statistically significant in the manufacturing industry. In the service and retail industry it is not significant in the UK and France, respectively. Second, as far as the role of the cash flows is concerned, results indicate that there exist industry differences that were not observed when the previous hypotheses were tested. Specifically, the level of cash flows seems to be more important to investors in the manufacturing industry. In the Anglo-Saxon countries, the UK and the USA, it is positive and statistically significant (0.25 and 0.266). Results in these Anglo-Saxon countries also indicate that the level of cash flows plays more important role to investors compared to the service industry. These results are consistent with my expectations since firms in the manufacturing have much more accruals due to higher levels of property, plant, equipment and inventory. Since these type of firms have much higher accruals, earnings can be manipulated more in these industries and thus investors and analysts pay more attention to cash flows.

As far as the French results in Table 18 are concerned, they indicate that there is no statistically significant difference among the industries. These results are again consistent with the expectations since in code law countries there is less manipulation in financial reports. Third, as far as the model significance is concerned, in all three industries the models are highly statistically significant as it is shown by the p-values and the F-values of the model (always p-value = 0.000). The F-value is shown to be the highest in the manufacturing industry in all countries examined, and it is shown to be the lowest in the service industry. Fourth, in all countries examined the lowest R^2 is shown in the service industry. In two countries, the UK and

France, the highest overall R^2 is shown in the retail industry. These results indicate that the variability of the stock prices is the lowest in the service industry, when taking into consideration financial information, such as earnings and cash flows.

In summary, consistent with my hypothesis and my expectations, these results indicate that earnings and cash flow information is industry specific, that is investors and financial analysts pay different attention to earnings and cash flows depending on the industry they analyze. Specifically, investors value more the earnings in the service industry, partly because in that industry the manipulation of earnings is the least because there exist the least accruals (i.e. depreciation, amortization, inventories, etc). As far as the cash flow information is concerned, results indicate that investors value cash flow more in the manufacturing industry. This is not surprising, because as I have already argued in this industry investors and financial analysts expect greater manipulation of earnings due to much higher accruals (i.e. depreciation, amortization, inventories, etc), and thus analysts pay less attention to earnings and consequently pay more attention to cash flows.

6.3.3.2 Multivariate regression analysis results for examining the valuation of earnings and cash flows when the measurement interval increases.

Hypothesis 4 predicts that the value relevance of earnings and cash flows improves as the measurement interval increases. Results shown in Table 19 provide support for the research hypothesis that tests the theoretical model [67] developed in chapter III. It is argued that over longer measurement intervals, the importance of accruals will diminish because manipulation by managers will not affect longer run earnings and cash flows and therefore the association between security returns and earnings and cash flows is expected to improve. Cash flows suffer more from timing and matching problems over short measurement intervals because they have no accrual adjustments and the accruals associated with cash flows are long-term in nature and they do not reverse in the short-run (Dechow, 1994). On the other hand, the explanatory power of earnings compared to cash flows is expected to be the highest over short measurement intervals, because earnings include accruals that mitigate the timing and matching problems related to the organization's operating, investing and financing cash flows. Previous USA and UK studies showed that there is a relative increase in the explanatory power of earnings over longer measurement intervals (Easton et al., 1992; Charitou, 1997; Dechow, 1994). Thus far, there has been limited research on the value relevance i) of cash flows over long measurement intervals, and ii) of earnings and cash flows in the USA, the UK and France.

Results in Table 19 provide multivariate regression results over longer-return intervals. Thus far, results were presented using annual return windows. That means that all returns, earnings and cash flow variables included in the model were measured on an annual basis, i.e. the way they are reported in the annual reports of the firms. Results in this table are presented for measurement intervals of 1, 2, 3, 4 and 5 years, for each country. For example, to test the five year model all variables included in the model, returns, earnings and cash flows were measured

over a five year period., i.e. for the earnings variable the earnings of a five year period were added together. The same applies to cash flows and returns. Results in table 19 indicate the following: first, as expected, for all countries, the five-year models have the highest R^2 , compared to the other one to four year models. For example, for the one year models, the R^2 is 11.4%, 10.1% and 7%, for France, the UK and the USA respectively, whereas the five year model R^2 results are 32%, 35.2% and 27.8%, for France, the UK and the USA, respectively.

As it can be seen, by increasing the measurement interval from one year to five years, the explanatory power of the regression model increases about three times. From the practitioner point of view, it means that the annual earnings and cash flows explain about 11.4% of the variability of the security returns in France, but in a five-year period the same earnings and cash flows explain about 32% of the variability of stock returns. Second, again as hypothesized, in all countries, the explanatory power of the model increases when I increase the measurement interval. For example, in the UK, the R^2 is only 10.1% in the one year interval, and it goes up to 15.2%, 19.4%, 24.5% and finally to 35.2% when I increase the interval to two, three, four and five years. Third, in all models tested for all countries for all measurement intervals, the earnings variable is positive and statistically significant, as it was expected. Fourth, similar to the earnings variable, the cash flow variable is positive and statistically significant in all models tested in all three countries. Fifth, interestingly, the explanatory power of the model from one to five years increases the highest in the USA (almost quadruples, 7% to 27.8%), whereas increases the least in France (almost triples, 11.4% for the annual and 32% for the five year interval). These results are not that surprising and they are consistent with my expectation. These results are due to the fact that in the shorter run there is a greater manipulation of financial information in Anglo-Saxon countries than in more conservative countries such as France. Thus, in Anglo-Saxon countries, such as the USA and the UK, the increase in the value relevance of financial

information over longer-return windows is greater than in a code law country, such as France.

In summary, results in Table 19 provide support in favor of my research hypothesis 4 which states that as the measurement interval increases the role of both earnings and cash flows in explaining stock returns improves. This is due to the fact that in the longer run any manipulation by managers of any type of financial information is cancelled out, and thus earnings and cash flows are becoming smoother.

6.3.3.3 Multivariate regression analysis results for examining the valuation of earnings and cash flows when the earnings are transitory.

Hypothesis 5 predicts that the value relevance of earnings decreases when earnings are transitory and thus, the value relevance of cash flows is expected to improve in all three countries when earnings are transitory. This research hypothesis tests the theoretical model [58] developed earlier in this study in chapter III.

The issue of the earnings permanence has raised the stimulus in the present study in examining the role of operating cash flows when earnings are transitory. As Cheng, Liu and Schafer (1996) argue, earnings may contain transitory items with limited valuation implications. For example, transitory items that may be included are accruals such as losses due to restructuring, current recognition through sale of assets of previous' period's, increases in market value, one-time impact on income from changes in accounting standards etc. Moreover, because of compensation contracts and debt covenants are usually based on profit, incentives exist for managers to introduce transitory elements in earnings and thus manipulate earnings.

Results in Table 20 provide evidence to support hypothesis 5, that is, when earnings are transitory the role of earnings in stock markets decreases and the role of cash flows improves.

Consistent with prior studies and with my theoretical framework, I included in my multivariate regression model in Table 20 both the level and changes of earnings and cash flows (Cheng, Liu and Schafer, 1996), in order to characterise the unexpected components of earnings and the unexpected components of cash flows from operations. This is done in order to test the hypothesis that when earnings are transitory the earnings response coefficients on both levels and changes will have reduced significance in explaining security returns. In this situation the importance of cash flows from operations will be greater. Therefore, in the model in Table 20 and in the theoretical model [58] presented in a previous chapter, the coefficients $c_{1t} + c_{2t}$ and $c_{3t} + c_{4t}$ represent the estimates of the earnings and cash flow response coefficients when earnings are mainly permanent. The coefficients $c_{5t} + c_{6t}$ and $c_{7t} + c_{8t}$ capture the additional information content of earnings and cash flows for firms with predominantly transitory earnings. It is expected that $c_{5t} + c_{6t}$ to be negative and $c_{7t} + c_{8t}$ to be positive.

TABLE 20

Multivariate regression analysis results for all years for all firms for the UK, USA and France when earnings are transitory.

$$\text{MODEL RET}_{it} = c_0 + c_1 E_{it} + c_2 \Delta E_{it} + c_3 \text{CFO}_{it} + c_4 \Delta \text{CFO}_{it} + c_5 E_{it} * D + c_6 \Delta E_{it} * D + c_7 \text{CFO}_{it} * D + c_8 \Delta \text{CFO}_{it} * D + e_{it}$$

Earnings are transitory as defined in Chapter IV, methodology. Transitory if $\Delta E / \text{Pt-1}$ is above median, and permanent if $\Delta E / \text{Pt-1}$ is below median where E: operating earnings, ΔE : change in earnings, CFO: operating cash flows, ΔCFO = change in operating earnings, RET= security returns D: dummy variable that takes the value of 1 if earnings are transitory and it takes the value of zero if earnings are permanent.

*, **, *** Statistically significant at $\alpha = 0.01, 0.05$ and 0.10 respectively

Specifically, results in Table 20 indicate the following. First, as expected, the sum of the coefficients of earnings (c_3+c_4) are positive and statistically significant in all three countries, the USA, the UK and France. These results indicate that in all three countries, the earnings are taken into consideration in the valuation of stock prices by security analysts and investors. Second, as expected, the sum of the coefficients of cash flows is positive and statistically significant in all three countries. Again, these results show that cash flows are important to security analysts and investors in the USA, the UK and France for stock valuation purposes. These results are consistent with the results provided thus far in all previous models. Third, the sum of the coefficients of earnings c_5+c_6 is negative and statistically significant in all three countries, the UK, the USA and France. These results are consistent with my expectations and with my hypothesis. These results mean that when earnings are transitory, i.e. when the variation of the earnings compare to stock prices is relatively high (in the present study above its median), then the stock market does not perceive this information as good news and the relative importance of earnings on stock prices decreases. This is measured by the sum of the coefficients of $(c_1+c_2) + (c_5+c_6)$. To give an example to make things clearer, let us assume that earnings are stable, not transitory. In that case the effect of earnings on stock prices in the UK will be 5.65 (sum of coefficients of earnings c_1+c_2). In contrast, when earnings are transitory for a firm in the UK, the effect of earnings on stock prices will not be 5.65 as above, but it will be 5.65 minus 4.933 (b_5+b_6), which is 0.68 only. So for, stable or permanent earnings firms in the UK the effect of earnings on stock prices is 5.65 whereas for transitory earnings firms the effect of earnings on stock prices in the UK is only 0.68.

As far as the USA and France is concerned the results are consistent with the UK results just discussed. Specifically, in the USA results indicate that when earnings are permanent the effect of earnings on stock prices is 5.88 (c_1+c_2), but when earnings are transitory (not

permanent), then the effect of earnings on stock prices is only 1.08 (i.e. 5.88 minus 4.8 or c_1+c_2 minus c_5+c_6). Results in France also support the results of the UK and the USA. French results in Table 20 indicate that when earnings are permanent, the effect of earnings on stock prices is 5.66 (c_1+c_2), but when earnings are transitory (not permanent), then the effect of earnings on stock prices is only 1.15 (ie., 5.66 minus 4.51 or c_1+c_2 minus c_5+c_6).

Fourth, as hypothesised, results in Table 20 support that the cash flow variables are taken into consideration by investors in investment decisions. Specifically, the sum of the coefficients of cash flows c_3+c_4 is positive and statistically significant in all three countries. For example, in the UK it is 0.15, in the USA it is 0.095 and in France is 0.18. These results are consistent with the results provided thus far in all previous models and hypotheses.

Fifth, as hypothesised, results in Table 20 support that when earnings are transitory, investors and security analysts in the UK and the USA pay more attention to cash flows. This is evidenced by the sum of the coefficients of cash flows c_7+c_8 . For example, in the UK when earnings are transitory, stock prices are affected more by 0.03 (c_7+c_8) from changes in cash flows. Similarly, in the USA, when earnings are transitory, stock prices are affected by 0.02 more from changes in cash flows. These results are very interesting because they show that in Anglo-Saxon countries such as the USA and the UK, investors do pay additional attention to cash flows because they do know that earnings are of lower value when they are transitory. On the other hand, consistent with prior evidence in previous models and tables of this study, French analysts and investors pay more attention to earnings because their code law system make financial reporting in France much more conservative, and thus the variability of earnings is not that high as the variability of earnings in the UK and the USA.

Sixth, in all countries examined, results support that the model is statistically significant and the variation of stock returns as explained by the R^2 is 15.6 in the UK, 12.8 in the USA and

17.2% in France.

In summary, results presented in Table 20 support my hypothesis that when earnings are transitory (not permanent), investors pay less attention to earnings and more attention to cash flows.

6.3.3.4 Multivariate Analysis regression results to test whether the valuation of earnings and cash flows is country specific.

Hypothesis 6 predicts that operating earnings and operating cash flows are associated with security returns, but the valuation of earnings and cash flows is expected to differ in these countries because their financial reporting systems differ. In the UK and in the USA the financial reporting system is less conservative, common law oriented, whereas in the non Anglo-Saxon country France, the financial reporting system is much more conservative and code law oriented.

Previous studies have not examined how earnings and cash flows are valued in France, the UK and the USA. Since I showed earlier in this study that there are significant financial reporting differences between these countries, I expect that these differences will affect the value relevance of earnings and cash flows in these countries. I hypothesized that the value relevance of earnings will be the highest in France since it has the most conservative financial reporting system. On the other hand, I expect that the value relevance of earnings will be the lowest in the UK and in the USA because they have the least conservative financial reporting system. Hence, I expect that cash flows will be the most (least) value relevant in the USA and the UK (France).

Statistical regression results presented in the present study support my hypothesis that earnings and cash flows are country specific, i.e. that they differ depending on the country.

Specifically, first, univariate results in Table 11 indicate that even though earnings and cash flows are important to investors and financial analysts in all three countries, the level of

earnings is considered somewhat more important to French investors (0.793) than to investors in the USA (0.759) and the UK (0.767).

Second, univariate results in Table 11 support my hypothesis that cash flows are valued in all three countries but they are valued more by the investors in Anglo-Saxon countries than in non Anglo-Saxon countries like France. For example, in the UK and the USA the coefficient of the level of cash flows is 0.451 and 0.447, respectively, whereas in France the coefficient of cash flows is only 0.197. Similar results are provided for the coefficient of the changes in cash flows. In the UK and the USA the coefficient of the changes of cash flows is 0.202 and 0.196, respectively, whereas in France the coefficient of cash flows is only 0.072.

Third, multivariate results presented in Tables 12 to 17 support again my hypothesis that the investors in these countries value differently financial information such as earnings and cash flows due to the financial reporting differences in these countries. Specifically, results in Table 12 indicate that total earnings, as measured by the sum of the level and changes of earnings (b_1+b_2), is valued by investors in all three countries, but results show that earnings are valued more in France and less in the Anglo-Saxon countries. Specifically, b_1+b_2 in France is 1.026 whereas in the USA and the UK is 1.004 and 0.89 respectively. These results are also supported by the R^2 of the models in each country. As it can be seen in Table 12 the highest R^2 is in the French model (14.3%), whereas in the UK and the USA is lower (10% and 8.4%, respectively). As already discussed, these results are due to the fact that the financial reporting in the Anglo-Saxon countries is much more liberal (less conservative) and managers may manipulate easier the financial statements.

Fourth, multivariate results presented in Table 12 support again my hypothesis that investors in these countries value differently cash flows due to the financial reporting differences in these countries. Specifically, results indicate that total cash flows, as measured by the sum of

the level and changes of cash flows (b_3+b_4), is valued by investors in all three countries, but results show that cash flows are valued more in the Anglo-Saxon countries and less in France. Specifically, the sum of the coefficients b_3+b_4 in France is 0.188 whereas in the USA and the UK it is 0.426 and 0.447, respectively. These results are also supported by the R^2 of the models in each country. As it can be seen in Table 12 the lowest R^2 is in the French model (2%), whereas in the UK and in the USA is higher (6.1% and 3.3%, respectively). As it has already been discussed, these results are due to the fact that the financial reporting in the Anglo-Saxon countries is much more liberal (less conservative) and managers may manipulate easier the financial statements, and since earnings are expected to be of lower quality in these countries, financial analysts and investors are expected to pay more attention to cash flows.

Fifth, results in Tables 13 to 17 support the hypothesis that when earnings and cash flows are taken together by investors and financial analysts, these stakeholders pay more attention to earnings but less attention to cash flows in France. The opposite happens in the Anglo-Saxon countries, namely, the USA and the UK. These results are consistent with the previous discussion. Specifically, results in Table 14 indicate that the earnings coefficient is the highest in France ($b_1+b_2 = 1.01$), whereas the earnings coefficient for the USA and the UK is 0.933 and 0.725, respectively. As far as the importance of cash flows is concerned, when earnings are considered, results are consistent with my expectations that is, cash flows are more important in the Anglo-Saxon countries USA and UK than in France. Specifically, the cash flow coefficients are low and insignificant in France ($b_3+b_4=0.013$), whereas the cash flow variable is valued highly by investors in the UK and USA (b_3+b_4 is 0.209 and 0.091 in UK and USA respectively).

Sixth, results in Tables 14 to 17 show that when taken together the earnings and cash flow information is perceived more important in France rather than in the Anglo-Saxon countries. This contention is supported by the R^2 s presented in Table 14. As it can be seen the

French model has the highest R^2 (17.90%) whereas the UK and the USA models have R^2 of 11% and 8.90%, respectively. These results are possibly due to the fact that in Anglo-Saxon countries there is greater manipulation of financial information by managers.

Seventh, when I proceeded further to examine additional factors that may affect the importance of earnings and cash flows in these countries, one of the factors I took into consideration was the industry the firm belongs to. For example, I argued that industries have different financial characteristics. Manufacturing firms, for example, are more capital intensive compared to retail and service organizations. Capital intensiveness may lead to greater need for cash flows for reinvestment purposes. Moreover, manufacturing firms have greater depreciation expenses and thus the differences between earnings and cash flows in manufacturing firms may be greater, compared to the retail and service firms. Furthermore, manufacturing and retail firms are expected to maintain higher inventory levels compared to service organizations. This difference in the inventory levels may lead to greater differences between earnings and cash flows in these two industries if there are great variations in inventory levels from year to year. For example, great increases in inventory levels in one year, assuming cash was used to manufacture or acquire this inventory will lead to a reduction in cash flows. My results in Table 18 support the above arguments and moreover support that earnings and cash flows are industry specific and moreover these results were also shown to be country specific. Specifically, the results show that in all industries the French model has the highest explanatory power as measured by the R^2 . This result is mostly due to the more usefulness of earnings to investors in France (see the coefficients of earnings b_1 and b_2). Also, as expected, results indicate that the cash flow information is more useful to the UK and the USA investors than to French investors in all industries examined, and more importantly in the manufacturing and retail industries where more discretion and manipulation exists in their financial reporting systems. For example, in the

manufacturing industry the coefficient of the level of cash flows is 0.266 and 0.25 for the USA and the UK respectively, whereas it is only 0.06 in the French model.

Eighth, when I examined the importance of earnings and cash flows in all three countries over a longer period of time (more than a year and up to five years), my results again support the hypothesis that investors in these three countries perceive earnings and cash flows differently.

Interestingly, the importance of earnings and cash flows from one to five years, as measured by the R^2 , increases the highest in the USA (almost quadruples, 7% to 27.8%), whereas increases the least in France (almost triples, 11.4% for the annual and 32% for the five year interval). These results are not that surprising in that in Anglo-Saxon countries such as the USA and the UK the increase is greater than in a code law country such as France. This is due to the fact that in the shorter run there is a greater manipulation of financial information in Anglo-Saxon countries than in more conservative countries such as France.

Nine, when I examine the importance of earnings and cash flows to investors and financial analysts in cases where the earnings information is transitory (not permanent or non stable or with very high variability), my results indicate that earnings and cash flows are perceived differently by investors, depending on the country to which they belong. Specifically, when earnings are transitory, investors in Anglo-Saxon countries penalize more these firms because the effect of earnings on stock returns is much more negative ($c5+c6 = -4.933$ and -4.8 for UK and USA, respectively, whereas it is only -4.51 for France).

Tenth, as hypothesised, results in Table 20 support the proposition that when earnings are transitory, investors and security analysts in the UK and the USA pay more attention to cash flows. This is evidenced by the sum of the coefficients of cash flows $c7+c8$. For example, in the UK when earnings are transitory, stock prices are affected more, by 0.03 ($c7+c8$) from changes in cash flows. Similarly, in the USA, when earnings are transitory, stock prices are affected by 0.02

more from changes in cash flows. These results are very interesting because they show that in Anglo-Saxon countries such as the USA and the UK, investors do pay additional attention to cash flows because they do know that earnings are of lower value when they are transitory. On the other hand, consistent with previous evidence and with evidence offered earlier in this study, French analysts and investors do pay more attention to earnings because their code law system makes financial reporting in France much more conservative, and thus the variability of earnings is not that high as the variability of earnings in the UK and the USA.

6.4 Summary of the empirical results

In summary, evidence provided in this study supports that indeed there are substantial differences in the way investors and financial analysts perceive financial information such as earnings and cash flows in the UK, France and the USA. These results are consistent with the six hypotheses proposed in this dissertation. Specifically, first results indicate that indeed both earnings and cash flows are taken into consideration by investors in their investment decisions. Second, given cash flows, results show that earnings are always very important to investors and financial analysts for investment purposes; given earnings though results show that cash flows are more important to investors in the Anglo-Saxon countries, possibly due to the lower importance that investors place on the manipulated earnings in these less conservative countries. As far as France is concerned, results reveal that investors place much more attention to earnings and little or no attention to cash flows. Third, results show that the value relevance of earnings and cash flows is industry specific. Fourth, evidence shows that investors pay more attention to longer-run earnings and cash flows rather than to shorter-run financial information. Fifth, results support that when earnings are transitory (not stable), investors pay more attention to cash flows and less attention to earnings. Sixth, results show that the value relevance of earnings and cash flows is

country specific. Specifically, results indicate that earnings are valued more in France and less in the Anglo-Saxon countries, due to the fact that the financial reporting in the Anglo-Saxon countries is much more liberal (less conservative) and managers may manipulate easier financial information. Moreover, as hypothesized, results show that cash flows are the most (least) value relevant in the USA and the UK (France).

CHAPTER VII

CONCLUSIONS

In this dissertation I have examined and tested theoretically and empirically six major hypotheses that relate to the role of financial information, and especially earnings and cash flows in three countries, two Anglo-Saxon, the UK and the USA and one code law country, France. A theoretical framework has been developed in this study in order to be able to build up my research hypotheses.

The results of this study have practical implications as well and should be of great importance to the major stakeholders such as investors, creditors, financial analysts, especially with the latest events that are taking place, and the major collapses of giant organizations worldwide such as Enron, Kmart, Vivendi, Parmalat and Worldcom among others. Regulatory bodies, investors, financial analysts and the financial press, blamed among others, the possible manipulation of financial information supplied to the investors by these organizations. The question raised, is whether this type of information is taken into consideration by investors in their investment decisions.

Statistical multiple and simple regression analysis was undertaken in this dissertation to test the major hypotheses of the study. A sample of 36,695 USA, 4,234 UK and 1,181 French firm-year observations were used to test the research hypotheses.

The empirical results presented in this dissertation support the proposed research hypotheses. More specifically, the major conclusions of the empirical results are summarized as

follows. First, empirical evidence in this dissertation confirms previous empirical evidence that both earnings and cash flows are associated with stock returns in all countries examined, namely, the USA, the UK and France. These results are also consistent with real world practice that financial analysts do take into consideration these financial variables in their investment decisions. Second, even though empirical evidence shows that both earnings and cash flows are valued in the capital markets, the question of interest is whether both earnings and cash flows are valued equally by financial analysts and investors. Empirical evidence in this dissertation reconfirmed previous USA evidence that earnings are valued more than cash flows in the marketplace. UK results were also consistent with USA results. In contrast, French evidence showed that investors in French capital markets pay little or no attention to cash flows, beyond earnings.

In order to test the robustness of my results I proceeded to examine whether the value relevance of earnings and cash flows depends on some contextual factors, such as a) the industry to which the firm belongs, b) the return window, and c) the transitoriness of earnings.

As far as the first issue is concerned, the research question raised is whether the value relevance of earnings depends on the industry to which the organization belongs. That is, do investors value more earnings and cash flows if the firm belongs in the retail, manufacturing or in the service industry? My empirical results showed that investors value more the earnings in the service industry, partly because in that industry the manipulation of earnings is the least because there exist the least accruals (i.e. depreciation, inventories, etc). As far as the cash flow information is concerned, results indicate that investors value cash flow more in the manufacturing industry. This is not surprising, because in that industry investors and financial analysts expect greater manipulation of earnings due to much higher accruals (i.e. depreciation, inventories, etc), and thus analysts pay less attention to earnings and consequently pay more

attention to cash flows.

Beyond the industry factor, I proceeded a step further to test whether investors pay more attention to the aggregate (long-time horizon) earnings and cash flows rather than to shorter-run (annual) financial information. As hypothesized, my statistical results for the three countries support that earnings and cash flows are more value relevant over the longer horizon. These results are due to the fact that both earnings and cash flows have timing and matching problems over the shorter run and thus earnings can be manipulated easier over a shorter horizon. On the other hand, over a longer-time horizon manipulation problems of earnings are mitigated. As far as cash flows are concerned, over a longer horizon are becoming smoother and thus they are more value relevant.

In addition to the aforementioned industry and long-horizon contextual factors, I also tested whether investors value earnings more (less) when this measure is permanent (transitory). If indeed investors do not pay that much attention to transitory earnings, do they pay more attention to cash flows when earnings are transitory? Results show that in all three countries, the USA, the UK and France, investors penalize firms with transitory earnings and pay more attention to cash flows in making their investment decisions. These results are not surprising because very high variability in earnings makes it very difficult for investors to rely on that financial measure and thus investors pay more attention to a relatively more permanent figure, namely cash flows.

Furthermore, one of the major objectives of this study was to examine whether earnings and cash flows are valued equally in the three countries under investigation. In a previous section of this dissertation I hypothesized that the value relevance of earnings will be the highest in code law countries, such as France since it has the most conservative financial reporting system. On the other hand, I hypothesized that the value relevance of earnings will be the lowest in common

law countries, namely in the UK and the USA, because they have the least conservative financial reporting system. Hence, I expect that cash flows will be the most (least) value relevant in the USA and the UK (France). Empirical results in this study supported the aforementioned hypotheses. Specifically, empirical results support the following:

First, multivariate results indicate that earnings are valued more in France and less in the Anglo-Saxon countries. These results may be due to the fact that the financial reporting in the Anglo-Saxon countries is much more liberal (less conservative) and managers may manipulate more the financial statements.

Second, multivariate results indicate that cash flows are valued by investors in all three countries, but results show that cash flows are valued more in the Anglo-Saxon countries (e.g. the USA and the UK) and less in France. As it has already been discussed, these results may be due to the fact that in Anglo-Saxon countries managers may manipulate more earnings, and thus financial analysts and investors pay more attention to cash flows because earnings are perceived to be of lower quality in these countries. Third, regarding industry differences within each country, results show that in all industries, the French model had the highest explanatory power, i.e. R^2 . These results may be due to the fact that French investors perceive of higher quality earnings measures. Also, as expected, results indicate that the cash flow information is more useful to the UK and the USA investors than to French investors in all industries examined, and more importantly in the manufacturing and retail industries where more discretion and manipulation exists in their financial reporting systems.

Fourth, when I examined the importance of earnings and cash flows in all three countries over a longer period of time (more than a year and up to five years), my results again supported the hypothesis that investors in these three countries perceive earnings and cash flows differently. Interestingly, the importance of earnings and cash flows from one to five years, as measured by

the R^2 , increases the highest in the USA, whereas increases the least in France. This evidence is consistent with my previous results that showed that in the shorter run there is a greater manipulation of financial information in Anglo-Saxon countries than in more conservative countries such as France. Fifth, when I examined the importance of earnings and cash flows to investors and financial analysts in cases where the earnings information is transitory, results indicated that investors in Anglo-Saxon countries penalize more the firms with non-permanent earnings, because the effect of earnings on stock returns is much more negative.

Furthermore, as hypothesized, results support that when earnings are transitory, investors and security analysts in the UK and the USA pay more attention to cash flows because they know that earnings are of lower quality when they are transitory. On the other hand, consistent with my expectations, French analysts and investors pay more attention to their earnings because their conservative code law system makes earnings smoother.

Moreover, the results of this study have important practical implications as well. Since the evidence in this dissertation supports that there are substantial differences in the way capital market participants perceive financial information, such as earnings and cash flows in the UK, France and the USA, investors, financial and credit analysts should be very cautious when making investment or credit decisions. Thus, these capital market participants should take seriously into consideration, among others, the relevant factors examined in this study, such as how earnings and cash flow information is perceived in different industries, how earnings and cash flows are valued when earnings is transitory and how financial information improves in quality when it is evaluated on a longer basis. Furthermore, investors, financial analysts and credit analysts should be very cautious in their decision making when the earnings are transitory, since evidence shows that capital market participants penalize those kind of firms and instead they pay much more attention to cash flow information.
